Contents

1. Introduction to Oracle Tuxedo Programming

Oracle Tuxedo Distributed Application Programming	1-1
Communication Paradigms	1-2
Oracle Tuxedo Clients	1-4
Oracle Tuxedo Servers	1-5
Basic Server Operation	1-6
Servers as Requesters	1-7
Oracle Tuxedo API: ATMI	1-7

2. Programming Environment

Updating the UBBCONFIG Configuration File	2-1
Setting Environment Variables	2-5
Defining Equivalent Data Types	2-9
Starting and Stopping the Application	2-10

3. Managing Typed Records

Overview of Typed Records	3-1
Defining Typed Records	3-6
Using a VIEW Typed Record	3-7
Setting Environment Variables for a VIEW Typed Record	3-7
Creating a View Description File	3-8
Executing the VIEW Compiler	3-11
Using an FML Typed Record	3-13

Setting Environment Variables for an FML Typed Record	3-14
Creating a Field Table File	3-14
Initializing a Typed Record	3-16
Creating an FML Header File	3-19
Using an XML Typed Record	3-20

4. Writing Clients

Joining an Application	4-1
Using Features of the TPINFDEF-REC Record	4-3
Client Naming	4-4
Unsolicited Notification Handling	4-5
System Access Mode	4-6
Resource Manager Association	4-7
Client Authentication	4-7
Leaving the Application	4-8
Building Clients	4-8
See Also	4-10
Client Process Examples	4-10

5. Writing Servers

Oracle Tuxedo System Controlling Program	5-1
System-supplied Server and Services	5-3
System-supplied Server: AUTHSVR()	5-3
System-supplied Services: TPSVRINIT Routine	5-3
Receiving Command-line Options	5-4
Opening a Resource Manager	5-6
System-supplied Services: TPSVRDONE Routine	5-8
Guidelines for Writing Servers	5-9

Defining a Service	5-11
Terminating a Service Routine	5-19
Sending Replies	5-19
Invalidating Descriptors	5-25
Forwarding Requests	5-26
Advertising and Unadvertising Services.	5-29
Advertising Services	5-30
Unadvertising Services	5-30
Example: Dynamic Advertising and Unadvertising of a Service	5-31
Building Servers	5-32
See Also.	5-34

6. Writing Request/Response Clients and Servers

Overview of Request/Response Communication	6-1
Sending Synchronous Messages.	6-2
Example: Using the Same Record for Request and Reply Messages	6-3
Example: Sending a Synchronous Message with TPSIGRSTRT Set	6-6
Example: Sending a Synchronous Message with TPNOTRAN Set	6-8
Sending Asynchronous Messages.	6-10
Sending an Asynchronous Request	6-11
Getting an Asynchronous Reply	6-14
Setting and Getting Message Priorities.	6-15
Setting a Message Priority.	6-15
Getting a Message Priority	6-17

7. Writing Conversational Clients and Servers

Overview of Conversational Communication	7-1
Joining an Application	7-3

Establishing a Connection	7-3
Sending and Receiving Messages	7-4
Sending Messages	7-5
Receiving Messages	7-6
Ending a Conversation	7-7
Example: Ending a Simple Conversation	7-8
Example: Ending a Hierarchical Conversation	7-9
Executing a Disorderly Disconnect	7-10
Building Conversational Clients and Servers	7-11
Understanding Conversational Communication Events	7-11

8. Writing Event-based Clients and Servers

Overview of Events	8-1
Unsolicited Events	8-2
Brokered Events	8-2
Notification Actions	8-2
EventBroker Servers	8-3
System-defined Events	8-4
Programming Interface for the EventBroker	8-4
Defining the Unsolicited Message Handler	8-5
Sending Unsolicited Messages	8-6
Broadcasting Messages by Name	8-6
Broadcasting Messages by Identifier	8-8
Checking for Unsolicited Messages	8-8
Getting Unsolicited Messages	8-10
Subscribing to Events	8-11
Unsubscribing from Events	8-15
Posting Events	8-15

9. Writing Global Transactions

What Is a Global Transaction?	9-1
Starting the Transaction	9-2
Terminating the Transaction.	9-10
Committing the Current Transaction.	9-11
Prerequisites for a Transaction Commit.	9-11
Two-phase Commit Protocol	9-12
Aborting the Current Transaction	9-13
Example: Committing a Transaction in Conversational Mode	9-14
Example: Testing for Participant Errors	9-15
Implicitly Defining a Global Transaction.	9-16
Defining Global Transactions for an XA-Compliant Server Group.	9-17
Testing Whether a Transaction Has Started	9-18
See Also.	9-20

10. Programming a Multithreaded and Multicontexted ATMI Application

Support for Programming a Multithreaded/Multicontexted ATMI Application	10-1
Platform-specific Considerations for Multithreaded/Multicontexted Applications	10-2
Planning and Designing a Multithreaded/Multicontexted ATMI Application.	10-3
What Are Multithreading and Multicontexting?	10-3
What Is Multithreading?	10-3
What Is Multicontexting?	10-5
Licensing a Multithreaded or Multicontexted Application	10-6
Advantages and Disadvantages of a Multithreaded/Multicontexted ATMI Application	10-7
Advantages of a Multithreaded/Multicontexted ATMI Application	10-7
Disadvantages of a Multithreaded/Multicontexted ATMI Application.	10-8
How Multithreading and Multicontexting Work in a Client	10-10

Start-up Phase	10-10
Client Threads Join Multiple Contexts	10-10
Client Threads Switch to an Existing Context.	10-11
Work Phase	10-11
Service Requests	10-11
Replies to Service Requests.	10-12
Transactions	10-12
Unsolicited Messages.	10-12
Userlog Maintains Thread-specific Information	10-14
Completion Phase	10-14
How Multithreading and Multicontexting Work in an ATMI Server	10-15
Start-up Phase	10-15
Work Phase	10-15
Server-dispatched Threads Are Used.	10-16
Application-created Threads Are Used	10-17
Bulletin Board Liaison Verifies Sanity of System Processes.	10-17
System Keeps Statistics on Server Threads.	10-18
Userlog Maintains Thread-specific Information	10-18
Completion Phase	10-18
Design Considerations for a Multithreaded and Multicontexted ATMI Application	10-19
Environment Requirements.	10-19
Design Requirements	10-20
Is the Task of Your Application Suitable for Multithreading and/or Multicontexting?	10-20
How Many Applications and Connections Do You Want?.	10-21
What Synchronization Issues Need to Be Addressed?	10-22
Will You Need to Port Your Application?.	10-22
Which Threads Model Is Best for You?	10-22

Interoperability Restrictions for Workstation Clients	10-22
Implementing a Multithreaded/ Multicontexted ATMI Application	10-23
Preliminary Guidelines for Programming a Multithreaded/Multicontexted ATMI Application	10-23
Prerequisites for a Multithreaded ATMI Application	10-23
General Multithreaded Programming Considerations.	10-24
Concurrency Considerations	10-24
Writing Code to Enable Multicontexting in an ATMI Client.	10-26
Context Attributes	10-26
Setting Up Multicontexting at Initialization	10-27
Implementing Security for a Multicontexted ATMI Client.	10-28
Synchronizing Threads Before an ATMI Client Termination	10-28
Switching Contexts	10-28
Handling Unsolicited Messages	10-31
Coding Rules for Transactions in a Multithreaded/Multicontexted ATMI Application 10-32	
Writing Code to Enable Multicontexting and Multithreading in an ATMI Server . .	10-33
Context Attributes	10-33
Coding Rules for a Multicontexted ATMI Server.	10-33
Initializing and Terminating ATMI Servers and Server Threads	10-34
Programming an ATMI Server to Create Threads.	10-35
Creating Threads	10-35
Associating Threads with a Context.	10-35
Sample Code for Creating an Application Thread in a Multicontexted ATMI Server . 10-36	
Writing a Multithreaded ATMI Client	10-38
Coding Rules for a Multithreaded ATMI Client	10-38
Initializing an ATMI Client to Multiple Contexts	10-39

Context State Changes for an ATMI Client Thread	10-40
Getting Replies in a Multithreaded Environment	10-41
Using Environment Variables in a Multithreaded and/or Multicontexted Environment	10-42
Using Per-context Functions and Data Structures in a Multithreaded ATMI Client	10-44
Using Per-process Functions and Data Structures in a Multithreaded ATMI Client	10-46
Using Per-thread Functions and Data Structures in a Multithreaded ATMI Client	10-47
Sample Code for a Multithreaded ATMI Client	10-47
Writing a Multithreaded ATMI Server	10-50
Compiling Code for a Multithreaded/Multicontexted ATMI Application.	10-50
Testing a Multithreaded/Multicontexted ATMI Application.	10-50
Testing Recommendations for a Multithreaded/Multicontexted ATMI Application	10-51
Troubleshooting a Multithreaded/Multicontexted ATMI Application	10-51
Improper Use of the TPMULTICONTXTS Flag to tpinit()	10-51
Calls to tpinit() Without TPMULTICONTXTS	10-51
Insufficient Thread Stack Size	10-52
Error Handling for a Multithreaded/Multicontexted ATMI Application	10-52

11. Managing Errors

System Errors	11-1
Abort Errors	11-3
Oracle Tuxedo System Errors	11-3
Communication Handle Errors.	11-3
Limit Errors.	11-4
Invalid Descriptor Errors.	11-4

Conversational Errors	11-4
Duplicate Object Error	11-5
General Communication Call Errors	11-5
TPESVCFAIL and TPESVCERR Errors	11-5
TPEBLOCK and TPGOTSIG Errors	11-6
Invalid Argument Errors.	11-6
No Entry Errors.	11-7
Operating System Errors.	11-7
Permission Errors	11-8
Protocol Errors	11-8
Queuing Error	11-8
Release Compatibility Error	11-8
Resource Manager Errors	11-9
Timeout Errors	11-9
Transaction Errors.	11-10
Typed Record Errors.	11-10
Application Errors.	11-11
Handling Errors.	11-11
Transaction Considerations.	11-12
Communication Etiquette	11-12
Transaction Errors.	11-13
Non-fatal Transaction Errors	11-13
Fatal Transaction Errors	11-14
Heuristic Decision Errors	11-15
Transaction Timeouts	11-16
TPCOMMIT Call	11-16
TPNOTRAN	11-16
TPRETURN and TPFORWAR Calls	11-17

tpterm() Function.	11-17
Resource Managers	11-18
Sample Transaction Scenarios	11-19
Called Service in Same Transaction as Caller	11-19
Called Service in Different Transaction with AUTOTRAN Set.	11-19
Called Service That Starts a New Explicit Transaction	11-20
Oracle TUXEDO System-supplied Subroutines	11-21
Central Event Log	11-21
Log Name	11-22
Log Entry Format	11-22
Writing to the Event Log.	11-23

12. COBOL Language Bindings for the Workstation Component

UNIX Bindings.	12-1
Writing Client Programs	12-1
Building Client Programs	12-1
Setting Environment Variables	12-2
Microsoft Windows Bindings	12-4
Writing Client Programs	12-4
Building Client Programs	12-4
Building ACCEPT/DISPLAY Clients.	12-5

Introduction to Oracle Tuxedo Programming

This topic includes the following sections:

- [Oracle Tuxedo Distributed Application Programming](#)
- [Communication Paradigms](#)
- [Oracle Tuxedo Clients](#)
- [Oracle Tuxedo Servers](#)
- [Oracle Tuxedo API: ATMI](#)

Oracle Tuxedo Distributed Application Programming

A *distributed application* consists of a set of software modules that reside on multiple hardware systems, and that communicate with one another to accomplish the tasks required of the application. For example, as shown in [Figure 1-1](#), a distributed application for a remote online banking system includes software modules that run on a bank customer's home computer, and a computer system at the bank on which all bank account records are maintained.

Figure 1-1 Distributed Application Example - Online Banking System

The task of checking an account balance, for example, can be performed simply by logging on and selecting an option from a menu. Behind the scenes, the local software module communicates with the remote software module using special application programming interface (API) routines.

The Oracle Tuxedo distributed application programming environment provides the API routines necessary to enable secure, reliable communication between the distributed software modules. This API is referred to as the [Application-to-Transaction Monitor Interface \(ATMI\)](#).

The ATMI enables you to:

- Send and receive messages between clients and servers, possibly across a network of heterogeneous machines
- Establish and use client naming and security features
- Define and manage transactions in which data may be stored in several locations
- Generically open and close a resource manager such as a Database Management System (DBMS)
- Manage the flow of service requests and the availability of servers to process them

Communication Paradigms

[Table 1-1](#) describes the Oracle Tuxedo ATMI communication paradigms available to application developers.

Table 1-1 Communication Paradigms

Paradigm	Description
Request/response communication	<p>Request/response communication enables one software module to send a request to a second software module and wait for a response. Can be synchronous (processing waits until the requester receives the response) or asynchronous (processing continues while the requester waits for the response).</p> <p>This mode is also referred to as client/server interaction. The first software module assumes the role of the client; the second, of the server.</p> <p>Refer to “Writing Request/Response Clients and Servers” on page 6-1 for more information on this paradigm.</p>
Conversational communication	<p>Conversational communication is similar to request/response communication, except that multiple requests and/or responses need to take place before the “conversation” is terminated. With conversational communication, both the client and the server maintain state information until the conversation is disconnected. The application protocol that you are using governs how messages are communicated between the client and server.</p> <p>Conversational communication is commonly used to buffer portions of a lengthy response from a server to a client.</p> <p>Refer to “Writing Conversational Clients and Servers” on page 7-1 for more information on this paradigm.</p>

Table 1-1 Communication Paradigms

Paradigm	Description
Application queue-based communication	<p>Application queue-based communication supports deferred or time-independent communication, enabling a client and server to communicate using an application queue. The Oracle Tuxedo/Q facility allows messages to be queued to persistent storage (disk) or to non-persistent storage (memory) for later processing or retrieval.</p> <p>For example, application queue-based communication is useful for enqueueing requests when a system goes offline for maintenance, or for buffering communications if the client and server systems are operating at different speeds.</p> <p>Refer to Using the ATMI/Q Component for more information on the /Q facility.</p>
Event-based communication	<p>Event-based communication allows a client or server to notify a client when a specific situation (event) occurs.</p> <p>Events are reported in one of two ways:</p> <ul style="list-style-type: none">• Unsolicited events are unexpected situations that are reported by clients and/or servers directly to clients.• Brokered events are unexpected situations or predictable occurrences with unpredictable timeframes that are reported by servers to clients indirectly, through an “anonymous broker” program that receives and distributes messages. <p>Event-based communication is based on the Oracle Tuxedo EventBroker facility.</p> <p>Refer to “Writing Event-based Clients and Servers” on page 8-1 for more information on this paradigm.</p>

Oracle Tuxedo Clients

An Oracle Tuxedo ATMI *client* is a software module that collects a user request and forwards it to a server that offers the requested service. Almost any software module can become an Oracle Tuxedo client by calling the ATMI client initialization routine and “joining” the Oracle Tuxedo application. The client can then exchange information with the server.

The client calls the ATMI termination routine to “leave” the application and notify the Oracle Tuxedo system that it (the client) no longer needs to be tracked. Consequently, Oracle Tuxedo application resources are made available for other operations.

The operation of a basic client process can be summarized by the pseudo-code shown in [Listing 1-1](#).

Listing 1-1 Pseudo-code for a Client

```
START PROGRAM
enroll as a client of the BEA TUXEDO application
place initial client identification in data structure
perform until end
get user input
place user input in DATA-REC
send service request
receive reply
pass reply to the user
end perform
leave application
END PROGRAM
```

Most of the actions described in the above listing are implemented with [ATMI](#) calls. Others—placing the user input in `DATA-REC` and passing the reply to the user—are implemented with COBOL routines.

An ATMI client may send and receive any number of service requests before leaving the application. The client may send these requests as a series of request/response calls or, if it is important to carry state information from one call to the next, by establishing a connection to a conversational server. In both cases, the logic in the client program is similar, but different ATMI calls are required for these two approaches.

Before you can execute an ATMI client, you must run the `buildclient -C` command to compile it and link it with the Oracle Tuxedo ATMI and required libraries. Refer to [“Writing Clients” on page 4-1](#) for information on the `buildclient(1)` command.

Oracle Tuxedo Servers

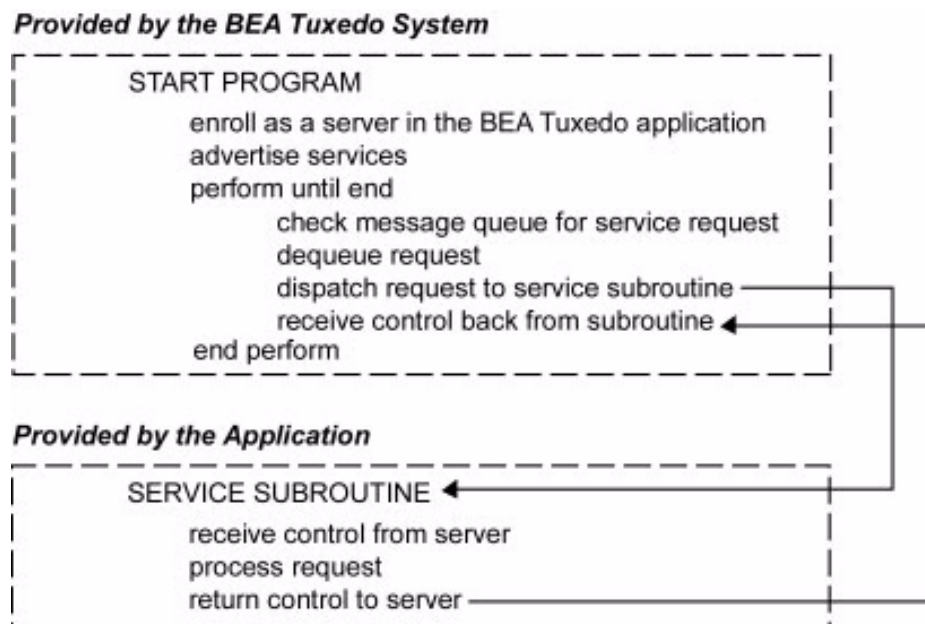

An Oracle Tuxedo ATMI *server* is a process that provides one or more *services* to a client. A service is a specific business task that a client may need to perform. Servers receive requests from clients and dispatch them to the appropriate service subroutines.

Basic Server Operation

To build server processes, applications combine their service subroutines with a controlling program provided by the Oracle Tuxedo system. This system-supplied controlling program is a set of predefined routines. It performs server initialization and termination and places user input in data structures that can be used to receive and dispatch incoming requests to service routines. All of this processing is transparent to the application.

[Figure 1-2](#) summarizes, in pseudo-code, the interaction between a server and a service subroutine.

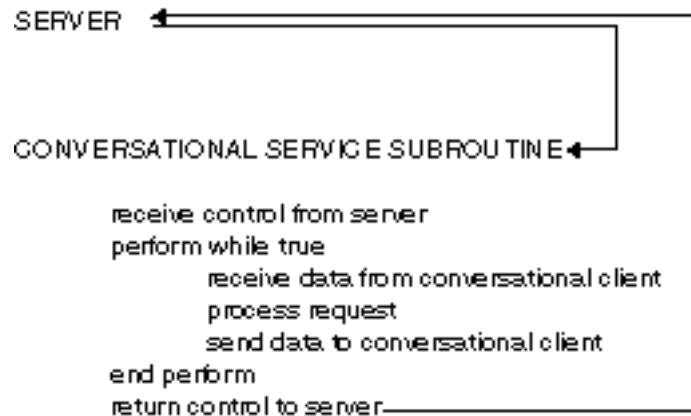

Figure 1-2 Pseudo-code for a Request/Response Server and a Service Subroutine

After initialization, an ATMI waits until a request message is delivered to its message queue, dequeues the request, and dispatches it to a service subroutine for processing. If a reply is required, the reply is considered part of request processing.

The conversational paradigm is somewhat different from request/response, as illustrated by the pseudo-code in [Figure 1-3](#).

Figure 1-3 Pseudo-code for a Conversational Service Subroutine

The Oracle Tuxedo system-supplied controlling program contains the code needed to enroll a process as an ATMI server, advertise services, and dequeue requests. ATMI calls are used in service subroutines that process requests. When you are ready to compile and test your service subroutines, you must link edit them with the server and generate an executable server. To do so, run the `buildserver -C` command.

Servers as Requesters

If a client requests several services, or several iterations of the same service, a subset of the services might be transferred to another server for execution. In this case, the server assumes the role of a client, or *requester*. Both clients and servers can be requesters; a client, however, can only be a requester. This coding model is easily accomplished using the Oracle Tuxedo ATMI calls.

Note: A request/response server can also forward a request to another server. In this case, the server does not assume the role of client (requester) because the reply is expected by the original client, not by the server forwarding the request.

Oracle Tuxedo API: ATMI

In addition to the COBOL code that expresses the logic of your application, you must use the Application-to-Transaction Monitor Interface (ATMI), the interface between your application and the Oracle Tuxedo system.

The ATMI is a reasonably compact set of calls used to open and close resources, begin and end transactions, and support communication between clients and servers. [Table 1-2](#) summarizes the ATMI calls. Each call is described in the *Oracle Tuxedo ATMI COBOL Function Reference*.

Table 1-2 Using the ATMI Calls

For a Task Related to . . .	Use This COBOL Function . . .	To . . .	For More Information, Refer to . . .
Client membership	TPINITIALIZE	Have a client join an application	“Writing Clients” on page 4-1
	TPTERM	Have a client leave an application	
Multiple application context management	TPGETCTXT(3cb1)	Retrieve an identifier for the current threads context	“Programming a Multithreaded and Multicontexted ATMI Application” on page 10-1
	TPSETCTXT(3cb1)	Set the current thread’s context in a multicontexted process	
Service entry and return	TPSVCSTART	Get service information	“Writing Servers” on page 5-1
	TPSVRINIT	Initialize a server	
	TPSVRDONE	Terminate a server	
	TPRETURN	End a service routine	
	TPFORWAR	Forward a request	
Dynamic advertisement	TPADVERTISE	Advertise a service name	“Writing Servers” on page 5-1
	TPUNADVERTISE	Unadvertise a service name	
Message priority	TPGPRIO	Get the priority of the last request	“Writing Servers” on page 5-1
	TPSPRIO	Set the priority of the next request	

Table 1-2 Using the ATMI Calls (Continued)

For a Task Related to . . .	Use This COBOL Function . . .	To . . .	For More Information, Refer to . . .
Request/Response communications	TPCALL	Initiate a synchronous request/response to a service	<ul style="list-style-type: none"> • “Writing Servers” on page 5-1 • “Writing Request/Response Clients and Servers” on page 6-1
	TPACALL	Initiate an asynchronous request (fanout)	
	TPGETRPLY	Receive an asynchronous response	
	TPCANCEL	Cancel an asynchronous request	
Conversational communications	TPCONNECT	Begin a conversation with a service	“Writing Conversational Clients and Servers” on page 7-1
	TPDISCON	Abnormally terminate a conversation	
	TPSEND	Send a message in a conversation	
	TPRECV	Receive a message in a conversation	
Reliable queuing	TPENQUEUE (3cbl)	Enqueue a message to a message queue	<i>Using the ATMI /Q Component</i>
	TPDEQUEUE (3cbl)	Dequeue a message from a message queue	

Table 1-2 Using the ATMI Calls (Continued)

For a Task Related to . . .	Use This COBOL Function . . .	To . . .	For More Information, Refer to . . .
Event-based communications	TPNOTIFY	Send an unsolicited message to a client	“Writing Event-based Clients and Servers” on page 8-1
	TPBROADCAST	Send messages to several clients	
	TPSETUNSOL	Set unsolicited message call-back	
	TPCHKUNSOL	Check the arrival of unsolicited messages	
	TPGETUNSOL	Get an unsolicited message	
	TPPOST	Post an event message	
	TPSUBSCRIBE	Subscribe to event messages	
	TPUNSUBSCRIBE	Unsubscribe to event messages	
Transaction management	TPBEGIN	Begin a transaction	“Writing Global Transactions” on page 9-1
	TPCOMMIT	Commit the current transaction	
	TPABORT	Roll back the current transaction	
	TPGETLEV	Check whether in transaction mode	
Resource management	TPOPEN(3cbl)	Open a resource manager	<ul style="list-style-type: none"> • “Programming a Multithreaded and Multicontexted ATMI Application” on page 10-1 • <i>Getting Started with Oracle Tuxedo CORBA Applications</i>
	TPCLOSE(3cbl)	Close a resource manager	

Table 1-2 Using the ATMI Calls (Continued)

For a Task Related to . . .	Use This COBOL Function . . .	To . . .	For More Information, Refer to . . .
Nontransactional blocking time management	TPGBLKTIME (3cbl)	Get blocktime value	<i>Oracle Tuxedo ATMI COBOL Function Reference</i>
	TPSBLKTIME (3cbl)	Set blocktime value in seconds or milliseconds	
Security	TPKEYOPEN (3cbl)	Open a key handle for digital signature generation, message encryption, or message decryption	<i>Using Security in CORBA Applications</i>
	TPKEYGETINFO (3cbl)	Get information associated with a key handle	
	TPKEYSETINFO (3cbl)	Set optional attributes associated with a key handle	
	TPKEYCLOSE (3cbl)	Close a key handle previously opened using TPKEYOPEN	

Programming Environment

This topic includes the following sections:

- [Updating the UBBCONFIG Configuration File](#)
- [Setting Environment Variables](#)
- [Defining Equivalent Data Types](#)
- [Starting and Stopping the Application](#)

Updating the UBBCONFIG Configuration File

The application administrator initially defines the configuration settings for an application in the UBBCONFIG configuration file. To customize your programming environment, you may need to create or update a configuration file.

If you need to create or update a configuration file, refer to the following guidelines:

- Copy and edit a file that already exists. For example, the file `ubbsbm` that comes with the `bankapp` sample application can provide a good starting point.
- Minimize complexity. For test purposes, set up your application as a shared memory, single-processor system. Use regular operating system files for your data.
- Make sure the `IPCKEY` parameter in the configuration file does not conflict with any other parameters being used at your installation. Check with your Oracle Tuxedo application administrator, and refer to *Setting Up an Oracle Tuxedo Application* for more information.

- Set the `UID` and `GID` parameters so that you are the owner of the configuration.
- Review the documentation. The configuration file is described in [UBBCONFIG\(5\)](#) in the *File Formats, Data Descriptions, MIBs, and System Processes Reference*.

[Table 2-1](#) summarizes the `UBBCONFIG` configuration file parameters that affect the programming environment. Parameters are listed by functional category.

Table 2-1 Programming-related UBBCONFIG Parameters by Functional Category

Functional Category	Parameter	Section	Description
Global resource limits	<code>MAXSERVERS</code>	<code>RESOURCES</code>	Specifies the maximum number of servers in the configuration. When setting this value, you need to consider the <code>MAX</code> values for all servers.
	<code>MAXSERVICES</code>	<code>RESOURCES</code>	Specifies the maximum total number of services in the configuration.
Data-dependent routing	<code>BUFTYPE</code>	<code>ROUTING</code>	List of types and subtypes of data records for which the specified routing entry is valid.
Link-level encryption	<code>MINENCRYPTBITS</code>	<code>NETWORK</code>	Sets the minimum encryption level that a process accepts.
	<code>MAXENCRYPTBITS</code>	<code>NETWORK</code>	Sets the maximum encryption level that a process accepts.

Table 2-1 Programming-related UBBCONFIG Parameters by Functional Category (Continued)

Functional Category	Parameter	Section	Description
Load balancing	LDBAL	RESOURCES	Flag for specifying whether or not load balancing is enabled. If enabled, the Oracle Tuxedo system attempts to balance requests across the network.
	NETLOAD	MACHINES	Numeric value that is added to the load factor of services that are remote from the invoking client, providing a bias for choosing a local server over a remote server. Load balancing must be enabled (that is, LDBAL must be set to Y).
	LOAD	SERVICES	Relative load factor associated with a service instance. The default is 50.
Security	AUTHSVC	RESOURCES	Specifies the name of an application authentication service that is invoked by the system for each client joining the system.
	SECURITY	RESOURCES	Specifies the type of application security to be enforced.

Table 2-1 Programming-related UBBCONFIG Parameters by Functional Category (Continued)

Functional Category	Parameter	Section	Description
Conversational communication	MAXCONV	RESOURCES	Sets the maximum number of simultaneous conversations for a single machine. You can specify a value between 0 and 32,767. The default is 64 if any conversational servers are defined in the <code>SERVERS</code> section; otherwise, the default is 1. The specified value can be overridden for each machine in the <code>MACHINES</code> section.
	CONV	SERVERS	Specifies whether or not conversational communication is supported. If this parameter is set to <code>N</code> or unspecified, a <code>TPCONNECT</code> call to a service fails.
	MIN/MAX	SERVERS	Specifies the minimum and maximum number of occurrences of the server to be started by <code>tmboot (1)</code> . If not specified, <code>MIN</code> defaults to 1 and <code>MAX</code> defaults to <code>MIN</code> . The same parameters are available for use with request/response servers. However, conversational servers are automatically spawned as needed. So if you set <code>MIN=1</code> and <code>MAX=10</code> , for example, <code>tmboot</code> starts one server initially. When a <code>TPCONNECT</code> call is made to a service offered by that server, the system starts a second copy of a server. As each copy is called, a new one is spawned, up to a limit of 10.

Table 2-1 Programming-related UBBCONFIG Parameters by Functional Category (Continued)

Functional Category	Parameter	Section	Description
Transaction management	AUTOTRAN	SERVICES	Controls whether a service routine is placed in transaction mode. If you set this parameter to Y, a transaction in the service subroutine is automatically started whenever a request message is received from another process.
Multithreaded servers	MAXDISPATCHTHREADS	SERVERS	Specifies the maximum number of concurrently dispatched threads that each server process may spawn.
	MINDISPATCHTHREADS	SERVERS	Specifies the number of server dispatch threads started on initial server boot.

The configuration file is an operating system text file. To make it usable by the system, you must execute the `tmloadcf(1)` command to convert the file to a binary file.

Setting Environment Variables

Initially, the application administrator sets the variables that define the environment in which your application runs. These environment variables are set by assigning values to the `ENVFILE` parameter in the `MACHINES` section of the `UBBCONFIG` file. (Refer to [Setting Up an Oracle Tuxedo Application](#) for more information.)

For the client and server routines in your application, you can update existing environment variables or create new ones. [Table 2-2](#) summarizes the most commonly used environment variables. The variables are listed by functional category.

Table 2-2 Programming-related Environment Variables

Function	Environment Variable	Defines the . . .	Used by . . .
Global	TUXDIR	Location of the Oracle Tuxedo system binary files.	Oracle Tuxedo application programs.
Configuration	TUXCONFIG	Location of the Oracle Tuxedo configuration file.	Oracle Tuxedo application programs.
Compiling	ALTCC ¹	Command that invokes the COBOL compiler. Default is <code>cobcc</code> . Specify <code>cobcc85</code> to use the Fujitsu NetCOBOL compiler.	<code>buildclient()</code> -C and <code>buildserver()</code> -C commands.
	ALTCFLAGS ¹	Link edit flags to be passed to the COBOL compiler. Link edit flags are optional.	<code>buildclient()</code> -C and <code>buildserver()</code> -C commands.
	COBOPT	Arguments that you may want to use on the compile command line. COBOPT cannot be used with Fujitsu NetCOBOL compiler. Please refer to Fujitsu's NetCOBOL manuals for COBOL environment variables.	<code>buildclient()</code> -C and <code>buildserver()</code> -C commands.
	COBCPY	Directories that contain a set of the COBOL COPY files to be used by the compiler. COBCPY cannot be used with Fujitsu NetCOBOL compiler. Please refer to Fujitsu's NetCOBOL manuals for COBOL environment variables.	<code>buildclient()</code> -C and <code>buildserver()</code> -C commands.

Table 2-2 Programming-related Environment Variables

Function	Environment Variable	Defines the . . .	Used by . . .
Data compression	TMCMPPRFM	Level of compression between 1 and 9.	Oracle Tuxedo application programs that perform data compression.
Load balancing	TMNETLOAD	Numeric value that is added to the load value for remote queues, making the remote queues appear to have more work than they actually do. As a result, even if load balancing is enabled, local requests are sent to local queues more often than to remote queues.	Oracle Tuxedo application programs that perform load balancing.

Table 2-2 Programming-related Environment Variables

Function	Environment Variable	Defines the . . .	Used by . . .
Record management	FIELDTBLS or FIELDTBLS32	Comma-separated list of field table filenames for FML and FML32 typed records, respectively. Required only for FML VIEW types.	FML and FML32 record types and FML VIEWS.
	FLDTBLDIR or FLDTBLDIR32	Colon-separated list of directories to be searched for the field table files for FML and FML32, respectively. For Windows 2003, a semicolon-separated list is used.	FML and FML32 record types and FML VIEWS.
	VIEWFILES or VIEWFILES32	Comma-separated list of allowable filenames for VIEW and VIEW32 typed records, respectively.	VIEW and VIEW32 record types.
	VIEWDIR or VIEWDIR32	Colon-separated list of directories to be searched for VIEW and VIEW32 files, respectively. For Windows 2003, a semicolon-separated list is used.	VIEW and VIEW32 record types.

1. On a Windows system, the ALTCC and ALTCLFLAGS environment variables are not applicable and setting them will produce unexpected results. You must compile your application first using a COBOL compiler and then pass the resulting object file to the `buildclient` or `buildserver` command.

If operating in a UNIX environment, add `$TUXDIR/bin` to your environment `PATH` to ensure that your application can locate the executables for the Oracle Tuxedo system commands. For more information on setting up the environment, refer to *Setting Up an Oracle Tuxedo Application*.

Defining Equivalent Data Types

Table 2-3 lists the C data types for which equivalent COBOL data types are available.

Table 2-3 COBOL Equivalents for C Data Types

C Data Type	Equivalent COBOL Data Type
float	COMP-1
double	COMP-2
long	S9(9) COMP-5 ¹
short	S9(4) COMP-5 ¹
dec_t	COBOL COMP-3 packed decimal field

1. COMP-5, provided for use with MicroFocus COBOL, allows the COBOL integer fields to match the data format of the corresponding C fields. The data type for VS COBOL II is COMP.

For storage efficiency, COBOL supports packed decimals: two decimal digits packed into each byte with the low-order half byte used to store the sign. The length of a packed decimal may be 1 to 9 bytes with storage available for 1 to 17 digits, including the sign.

The `dec_t` field is defined in a `VIEW`. The size is specified as two values separated by a comma. The first value indicates the total number of bytes occupied by the decimal in COBOL. The second value indicates the number of digits to the right of the decimal point in COBOL. You can use the following formula to convert the `dec_t` field to a COBOL declaration:

$$\text{dec_t}(m, n) \Rightarrow \text{S9}(2*m - (n+1), n)\text{COMP-3}$$

For example, a size specification of 6,4 in the `VIEW` indicates that there are 4 digits to the right of the decimal point and 7 digits to the left, and the last half byte is used to store the sign. A COBOL application programmer represents this as `9(7)V9(4)`, where the `V` represents the decimal point between each value. Note that `FML` does not support the `dec_t` type; if `FML`-dependent `VIEW`s are used, then each field must be mapped to a `C` type in the `VIEW` file. For instance, a packed decimal

can be mapped to an FML string field, and then the mapping functions can be used to do the conversion between formats.

Starting and Stopping the Application

To start the application, execute the `tmboot(1)` command. The command gets the IPC resources required by the application, and starts administrative processes and application servers.

To stop the application, execute the `tmsshutdown(1)` command. The command stops the servers and releases the IPC resources used by the application, except any that might be used by the resource manager, such as a database.

Managing Typed Records

This topic includes the following sections:

- [Overview of Typed Records](#)
- [Defining Typed Records](#)
- [Using a VIEW Typed Record](#)
- [Using an FML Typed Record](#)
- [Using an XML Typed Record](#)

Overview of Typed Records

In order to send data to another application program, the sending program first places the data in a record. Oracle Tuxedo ATMI clients use typed records to send messages to ATMI servers. The term “typed record” refers to a pair of COBOL records: a data record and an auxiliary type record. The data record is defined in static storage and contains application data to be passed to another application program. An auxiliary type record accompanies the data record. It specifies the interpretation and translation rules of the data record to be used by the Oracle Tuxedo system when passing the information between heterogeneous systems. Typed records make up one of the fundamental features of the distributed programming environment supported by the Oracle Tuxedo system.

Why *typed*? In a distributed environment, an application may be installed on heterogeneous systems that communicate across multiple networks using different protocols. Different types of records require different routines to initialize, send and receive messages, and encode and decode

data. Each record is designated as a specific type so that the appropriate routines can be called automatically without programmer intervention.

[Table 3-1](#) lists the typed records supported by the Oracle Tuxedo system and indicates whether or not:

- The record is *self-describing*; in other words, the record data type and length can be determined simply by (a) knowing the type and subtype, and (b) looking at the data.
- The record requires a subtype.
- The system supports data-dependent routing for the typed record.
- The system supports encoding and decoding for the typed record.

If any routing routines are required, the application programmer must provide them as part of the application.**Records.**

Table 3-1 Typed Buffers

Typed Record	Description	Self-Describing	Subtype	Data-Dependent Routing	Encoding/Decoding
CARRAY	<p>Undefined array of characters, any of which can be LOW-VALUE. This typed record is used to handle the data opaquely, as the Oracle Tuxedo system does not interpret the semantics of the array. Because a CARRAY is not self-describing, the length must always be provided during transmission. Encoding and decoding are not supported for messages sent between machines because the bytes are not interpreted by the system.</p>	No	No	No	No
FML (Field Manipulation Language)	<p>Proprietary Oracle Tuxedo system type of self-describing record in which each data field carries its own identifier, an occurrence number, and possibly a length indicator. T record offers data-independence and greater flexibility</p> <p>The FML record uses 16 bits for field identifiers and lengths of fields.</p> <p>Refer to “Using an FML Typed Record” on page 3-13 for more information.</p>	Yes	No	Yes	Yes
FML32	<p>Equivalent to FML but uses 32 bits for field identifiers and lengths of fields, which allows for larger and more fields and, consequently, larger overall records.</p> <p>However, the FML routines that are available for manipulating the FML typed record in the C programming language are not available in COBOL. The primary use of FML32 in COBOL is simply to work with C programs in which VIEW32 or FML32 typed records are used.</p> <p>Refer to “Using an FML Typed Record” on page 3-13 for more information.</p>	Yes	No	Yes	Yes

Table 3-1 Typed Buffers (Continued)

Typed Record	Description	Self-Describing	Subtype	Data-Dependent Routing	Encoding/Decoding
STRING	Array of characters that terminates with a LOW-VALUE character. The Oracle Tuxedo system can convert data automatically when data is exchanged by machines with different character sets.	No	No	No	No
VIEW	COBOL data structure defined by the application. VIEW types must have subtypes that designate individual data structures. A view description file , in which the fields and types that appear in the data structure are defined, must be available to client and server processes that use a data structure described in a VIEW typed record. Encoding and decoding are performed automatically if the record is passed between machines of different types. Refer to “Using a VIEW Typed Record” on page 3-7 for more information.	No	Yes	Yes	Yes
VIEW32	Equivalent to VIEW but uses 32 bits for length and count fields, which allows for larger and more fields and, consequently, larger overall records. The primary use of VIEW32 in COBOL is simply to work with C programs in which VIEW32 or FML32 typed records are used. Refer to “Using a VIEW Typed Record” on page 3-7 for more information.	No	Yes	Yes	Yes
X_COMMON	Equivalent to VIEW, but used for compatibility between COBOL and C programs. Field types should be limited to short, long, and string.	No	Yes	Yes	Yes

Table 3-1 Typed Buffers (Continued)

Typed Record	Description	Self-Describing	Subtype	Data-Dependent Routing	Encoding/Decoding
XML	<p>An XML document that consists of:</p> <ul style="list-style-type: none"> Text, in the form of a sequence of encoded characters A description of the logical structure of the document and information about that structure <p>The routing of an XML document can be based on element content, or on element type and an attribute value. The XML parser determines the character encoding being used; if the encoding differs from the native character sets (US-ASCII or EBCDIC) used in the Oracle Tuxedo configuration files (UBBCONFIG(5) and DMCONFIG(5)), the element and attribute names are converted to US-ASCII or EBCDIC. Refer to “Using an XML Typed Record” on page 3-20 for more information.</p>	No	No	Yes	No
X_OCTET	Equivalent to CARRAY.	No	No	No	No

All record types are defined in a file called `tmtpesw.c` in the `$TUXDIR/lib` directory. Only record types defined in `tmtpesw.c` are known to your client and server programs. You can edit the `tmtpesw.c` file to add or remove record types. In addition, you can use the `BUFTYPE` parameter (in `UBBCONFIG`) to restrict the types and subtypes that can be processed by a given service.

The `tmtpesw.c` file is used to build a shared object or dynamic link library. This object is dynamically loaded by both Oracle Tuxedo administrative servers, and application clients and servers.

Defining Typed Records

The `TPTYPE-REC` COBOL structure is used whenever sending or receiving application data.

The following table lists the `TPTYPE-REC` structure fields.

Field	Description
REC-TYPE	Specifies which record type the application wishes to send or receive.
SUB-TYPE	Specifies the subtype of the record type, if further classification is required (as it is, for example, in a <code>VIEW</code> record).
LEN	When data is being sent, specifies the number of bytes to be sent. After a successful transfer, <code>LEN</code> contains the number of bytes transferred. When data is being received, <code>LEN</code> in <code>TPTYPE-REC</code> specifies the number of bytes to be moved into the data record. After a successful call, <code>LEN</code> contains the number of bytes moved into the data record. If the size of the incoming message is larger than the size specified in <code>LEN</code> , the data is truncated, all data after the <code>LEN</code> length is reached is discarded, and <code>TPTYPE-STATUS</code> is set to <code>TPTRUNCATE</code> .

The following shows the `TPTYPE` data structure:

```

05 REC-TYPE PIC X(8).
   88 X-OCTET VALUE "X_OCTET".
   88 X-COMMON VALUE "X_COMMON".
05 SUB-TYPE PIC X(16).
05 LEN PIC S9(9) COMP-5.
   88 NO-LENGTH VALUE 0.
05 TPTYPE-STATUS PIC S9(9) COMP-5.
   88 TPTYPEOK VALUE 0.
   88 TPTRUNCATE VALUE 1.

```

Using a VIEW Typed Record

There are two kinds of `VIEW` typed records. The first, `FML VIEW`, is a COBOL record generated from an `FML` record. The second is simply an independent COBOL record.

The reason for converting `FML` records into COBOL records and back again (and the purpose of the `FML VIEW` typed records) is that `FML` functions are not available in the COBOL programming environment.

For more information on the `FML` typed record, refer to the *Oracle Tuxedo ATMI FML Function Reference*.

To use `VIEW` typed records, you must perform the following steps:

- [Set the appropriate environment variables.](#)
- [Describe each structure in view description files.](#)
- [Compile the view description files using `viewc -c`, the Oracle Tuxedo view compiler.](#) By running this command you will produce one or more COBOL `COPY` files (one per view), each of which contains data description records. These records can be used in the `LINKAGE` section or the `WORKING STORAGE` section of the `DATA DIVISION`, according to the demands of the program.

Setting Environment Variables for a VIEW Typed Record

To use a `VIEW` typed record in an application, you must set the following environment variables shown in [Table 3-2](#).

Table 3-2 Environment Variables for a VIEW Typed Record

Environment Variable	Description
<code>FIELDTBLS</code> or <code>FIELDTBLS32</code>	Comma-separated list of field table filenames for <code>FML</code> or <code>FML32</code> typed records. Required only for <code>FML VIEW</code> types.
<code>FLDTBLDIR</code> or <code>FLDTBLDIR32</code>	Colon-separated list of directories to search for the field table files for <code>FML</code> and <code>FML32</code> typed records. For Microsoft Windows, use a semicolon-separated list. Required only for <code>FML VIEW</code> types.

Table 3-2 Environment Variables for a VIEW Typed Record

Environment Variable	Description
VIEWFILES or VIEWFILES32	Comma-separated list of allowable filenames for VIEW or VIEW32 description files.
VIEWDIR or VIEWDIR32	Colon-separated list of directories to search for VIEW or VIEW32 files. For Microsoft Windows, use a semicolon-separated list.

Creating a View Description File

To use a VIEW typed record, you must define the COBOL record in a view description file. The view description file includes, a view for each entry, a view that describes the characteristic COBOL procedure mapping and the potential FML conversion pattern. The name of the view corresponds to the name of the copy file that is included in COBOL program.

The following format is used for each record in the view description file:

```
$ /* View structure */
VIEW viewname
  type      cname      ffname      count      flag      size      null
```

[Table 3-3](#) describes the fields that must be specified in the view description file for each COBOL record.

Table 3-3 View Description File Fields

Field	Description
<i>type</i>	Data type of the field. Can be set to short, long, float, double, char, string, or carray.
<i>cname</i>	Name of the field as it appears in the COBOL record.
<i>ffname</i>	If you will be using the FML-to-VIEW or VIEW-to-FML conversion routines, this field must be included to indicate the corresponding FML name. This field name must also appear in the FML field table file . This field is not required for FML-independent VIEWS.
<i>count</i>	Number of times field occurs.

Table 3-3 View Description File Fields (Continued)

Field	Description
<i>flag</i>	<p>Specifies any of the following optional flag settings:</p> <ul style="list-style-type: none"> • P—change the interpretation of the LOW-VALUE value • S—one-way mapping from fielded record to structure • F—one-way mapping from structure to fielded record • N—zero-way mapping • C—generate additional field for associated count member (ACM) • L—hold number of bytes transferred for STRING and CARRAY
<i>size</i>	For STRING and CARRAY record types, specifies the maximum length of the value. This field is ignored for all other record types.
<i>null</i>	<p>User-specified LOW-VALUE value, or minus sign (-) to indicate the default value for a field. LOW-VALUE values are used in VIEW typed records to indicate empty COBOL record members.</p> <p>The default LOW-VALUE value for all numeric types is 0 (0.0 for <code>dec_t</code>). For character types, the default LOW-VALUE value is '\0'. For STRING and CARRAY types, the default LOW-VALUE value is "".</p> <p>Constants used, by convention, as escape characters can also be used to specify a LOW-VALUE value. The view compiler recognizes the following escape constants: \ddd (where d is an octal digit), \0, \n, \t, \v, \r, \f, \\\, \', and \".</p> <p>You may enclose STRING, CARRAY, and LOW-VALUE values in double or single quotes. The view compiler does not accept unescaped quotes within a user-specified LOW-VALUE value.</p> <p>You can also specify the keyword NONE in the LOW-VALUE field of a view member description, which means that there is no LOW-VALUE value for the member. The maximum size of default values for string and character array members is 2660 characters. For more information, refer to the <i>Oracle Tuxedo ATMI FML Function Reference</i>.</p>

You can include a comment line by prefixing it with the # or \$ character. Lines prefixed by a \$ sign are included in the .h file.

[Listing 3-1](#) is an excerpt from an example view description file based on an FML record. In this case, the *fdbname* field must be specified and match that which appears in the corresponding [field table file](#). Note that the CARRAY1 field includes an occurrence count of 2 and sets the c flag to indicate that an additional count element should be created. In addition, the L flag is set to establish a length element that indicates the number of characters with which the application populates the CARRAY1 field.

Listing 3-1 View Description File for FML VIEW

```
$ /* View structure */
VIEW MYVIEW
#type      cname      fdbname    count    flag      size      null
float      float1     FLOAT1     1        -         -         0.0
double     double1    DOUBLE1    1        -         -         0.0
long       long1      LONG1     1        -         -         0
short      short1     SHORT1    1        -         -         0
int        int1       INT1      1        -         -         0
dec_t      dec1       DEC1      1        -         9,16      0
char       char1      CHAR1     1        -         -         '\0'
string     string1    STRING1    1        -         20        '\0'
carray     carray1    CARRAY1    2        CL        20        '\0'
END
```

[Listing 3-2](#) illustrates the same view description file for an independent VIEW.

Listing 3-2 View Description File for an Independent View

```
$ /* View data structure */
VIEW MYVIEW
#type      cname      fdbname    count    flag      size      null
float      float1     -          1        -         -         -
double     double1    -          1        -         -         -
long       long1      -          1        -         -         -
```

short	short1	-	1	-	-	-
int	int1	-	1	-	-	-
dec_t	dec1	-	1	-	9,16	-
char	char1	-	1	-	-	-
string	string1	-	1	-	20	-
carray	carray1	-	2	CL	20	-
END						

Note that the format is similar to the FML-dependent view, except that the *fdbname* and *null* fields are not relevant and are ignored by the `viewc` compiler. You must include a value (for example, a dash) as a placeholder in these fields.

Executing the VIEW Compiler

To compile a VIEW typed record, run the `viewc -C` command, specifying the name of the view description file as an argument. To specify an independent VIEW, use the `-n` option. You can optionally specify a directory in which the resulting output file should be written. By default, the output file is written to the current directory.

For example, for an FML-dependent VIEW, the compiler is invoked as follows:

```
viewc -C myview.v
```

Note: To compile a VIEW32 typed record, run the `viewc32 -C` command.

For an independent VIEW, use the `-n` option on the command line, as follows:

```
viewc -C -n myview.v
```

The output of the `viewc` command includes:

- One or more COBOL COPY files; for example, `MYVIEW.cbl`
- Header file containing a structure definition that may be used by application programs for C routines that share the same view
- Binary version of the source description file; for example, `myview.V`

Note: On case-insensitive platforms (for example, Microsoft Windows), the extension used for the names of such files is `vv`; for example, `myview.vv`.

[Listing 3-3](#) provides an example of the COBOL COPY file created by `viewc`.

Listing 3-3 COBOL COPY File Example

```
*    VIEWFILE: "myview.v"
*    VIEWNAME: "MYVIEW"
05 FLOAT1                      USAGE IS COMP-1.
05 DOUBLE1                     USAGE IS COMP-2.
05 LONG1                       PIC S9(9) USAGE IS COMP-5.
05 SHORT1                      PIC S9(4) USAGE IS COMP-5.
05 FILLER                      PIC X(02).
05 INT1                        PIC S9(9) USAGE IS COMP-5.
05 DEC1.
    07 DEC-EXP                  PIC S9(4) USAGE IS COMP-5.
    07 DEC-POS                  PIC S9(4) USAGE IS COMP-5.
    07 DEC-NDGTS                PIC S9(4) USAGE IS COMP-5.
*    DEC-DGTS is the actual packed decimal value
    07 DEC-DGTS                 PIC S9(1)V9(16) COMP-3.
    07 FILLER                   PIC X(07).
05 CHAR1                       PIC X(01).
05 STRING1                     PIC X(20).
05 FILLER                      PIC X(01).
05 L-CARRAY1 OCCURS 2 TIMES     PIC 9(4) USAGE IS COMP-5.
*    LENGTH OF CARRAY1
05 C-CARRAY1                   PIC S9(4) USAGE IS COMP-5.
*    COUNT OF CARRAY1
05 CARRAY1 OCCURS 2 TIMES      PIC X(20).
05 FILLER                      PIC X(02).
```

COBOL COPY files for views must be brought into client programs and service subroutines with COPY statements.

In the previous example, the compiler includes FILLER files so that the alignment of fields in COBOL code matches the alignment in C code.

The format of the packed decimal value, DEC1, is composed of five fields. Four fields—DEC-EXP, DEC-POS, DEC-NDGTS, and FILLER—are used only in C (they are defined in the dec_t type); they are included in the COBOL record for filler. Do not use these fields in COBOL applications.

The fifth field, `DEC-DGTS`, is used by the system to store the actual packed decimal value. You should use this value within the COBOL program. ATMI calls operate on the `DEC-DGTS` field to:

- Populate the field before the record is passed from a C program to a COBOL program.
- Convert the field back to the `dec_t` type when passed from the COBOL program to the C program.

The only restriction is that a COBOL program cannot directly pass a record to a C function outside of the ATMI interface because the decimal formats in the COBOL program and C function do not match.

Finally, note that the sample COBOL `COPY` file includes an `L-CARRAY1` length field that occurs twice, once for each occurrence of `CARRAY1`, and a `C-CARRAY1` count field.

`viewc` creates a C version of the header file that you can use to mix C and COBOL service and/or client programs.

Using an FML Typed Record

The FML interface was designed for use with the C language. For COBOL, routines are provided that allow you to convert a received FML record type to a COBOL record for processing, and then convert the record back to FML.

To use FML typed records, you must perform the following steps:

- [Set the appropriate environment variables.](#)
- [Describe the potential fields in an FML field table.](#)
- Initialize the FML record using `FINIT`.
- Create an FML header file and specify the header file in a `#include` statement C routines that share the same view in the application.

FML routines are used to manipulate typed records, including those that convert fielded records to C structures and vice versa. By using these functions, you can access and update data values

without having to know how data is structured and stored. For more information on FML routines, refer to the *Oracle Tuxedo ATMI FML Function Reference*.

Setting Environment Variables for an FML Typed Record

To use an FML typed record in an application program, you must set the following environment variables shown in [Table 3-4](#).

Table 3-4 FML Typed Record Environment Variables

Environment Variable	Description
FIELDTBLS or FIELDTBLS32	Comma-separated list of field table filenames for FML or FML32 typed records, respectively.
FLDTBLDIR or FLDTBLDIR32	Colon-separated list of directories to search for the field table files for FML and FML32, respectively. For Microsoft Windows, use a semicolon-separated list.

Creating a Field Table File

Field table files are always required when FML records and/or FML-dependent VIEWS are used. A field table file maps the logical name of a field in an FML record to a string that uniquely identifies the field.

The following format is used for the description of each field in the FML field table:

```
$ /* FML structure */  
  *base value  
  name      number      type      flags      comments
```

[Table 3-5](#) describes the fields that must be specified in the FML field table file for each FML field.

Table 3-5 Field Table File Fields

Field	Description
<i>*base value</i>	<p>Specifies a base for offsetting subsequent field numbers, providing an easy way to group and renumber sets of related fields. The <i>*base</i> option allows field numbers to be reused. For a 16-bit record, the base plus the relevant number must be greater than or equal to 100 and less than 8191. This field is optional.</p> <p>Note: The Oracle Tuxedo system reserves field numbers 1-100 and 6000-7000 for internal use. Field numbers 101-8191 are available for application-defined fields with FML; field numbers 101-33, 554, and 431, for FML32.</p>
<i>name</i>	Identifier for the field. The value must be a string of up to 256 characters, consisting of alphanumeric and underscore characters only.
<i>rel-number</i>	Relative numeric value of the field. This value is added to the current base, if specified, to calculate the field number.
<i>type</i>	Type of the field. This value can be any of the following: <i>char</i> , <i>string</i> , <i>short</i> , <i>long</i> , <i>float</i> , <i>double</i> , or <i>carray</i> .
<i>flag</i>	Reserved for future use. A dash (-) should be included as a placeholder.
<i>comment</i>	Optional comment.

All fields are optional, and may be included more than once.

[Listing 3-4](#) illustrates a field table file that may be used with the [FML-dependent VIEW example](#).

Listing 3-4 Field Table File for FML VIEW

#	name	number	type	flags	comments
	FLOAT1	110	float	-	-
	DOUBLE1	111	double	-	-
	LONG1	112	long	-	-
	SHORT1	113	short	-	-
	INT1	114	long	-	-
	DEC1	115	string	-	-
	CHAR1	116	char	-	-
	STRING1	117	string	-	-
	CARRAY1	118	carray	-	-

Initializing a Typed Record

An FML typed record must be initialized using the `FINIT` procedure. The `TPINIT` procedure takes the specified FML record (preferably aligned on a full-word boundary) and uses the value specified in the `FML-LENGTH` field in the `FMLINFO` record as the length.

If `TPNOCHANGE` is set, then any FML record received by a program (rather than created by the program) is initialized automatically. In this case, it is unnecessary to call `FINIT`.

[Listing 3-5](#) shows how to perform an initialization.

Listing 3-5 FML/VIEW Conversion

```
WORKING-STORAGE SECTION.  
*RECORD TYPE AND LENGTH

CALL "FVFTOS" USING MYFML MYVIEW FML-REC.
IF NOT FOK
    MOVE "FVFTOS Failed" TO LOGMSG-TEXT
    PERFORM DO-USERLOG
    PERFORM EXIT-PROGRAM
END-IF.

```

In the preceding listing, the `FVSTOF` procedure converts an `FML` record into a `VIEW` record. The view is defined by including the copy file generated by the view compiler. The `FML-REC` record provides the `VIEWNAME` and the `FML-MODE` transfer mode, which can be set to `FUPDATE`, `FOJOIN`, `FJOIN`, or `FCONCAT`. The actions associated with these modes are the same as those described in [Fupdate](#), [Fupdate32\(3fml\)](#), [Fojoin](#), [Fojoin32\(3fml\)](#), [Fjoin](#), [Fjoin32\(3fml\)](#), and [Fconcat](#), [Fconcat32\(3fml\)](#).

The `FVFTOS` procedure converts a `VIEW` record into an `FML` record. The parameters are the same as those for an `FVSTOF` procedure but you do not need to set `FML-MODE`. The system copies the fields from the fielded record into the structure, based on the element descriptions in the view. If there is no corresponding element in the COBOL record for a field in the fielded record, then the system ignores the field. If there is no corresponding field in the fielded record for an element specified in the COBOL record, the system copies a null value into the element. The null value used can be defined for each element in the view description.

To store multiple occurrences of a field in the COBOL record, a record element should be defined with `OCCURS`. If the number of occurrences of the field in the record is smaller than the number of occurrences of the element, the extra element slots are assigned null values. Alternatively, if the number of occurrences of the field in the record is higher than the number of occurrences of the element, then the surplus occurrences are ignored.

For `FML32` and `VIEW32`, the `FINIT32`, `FVSTOF32`, and `FVFTOS32` procedures should be used.

Upon successful completion, the system sets the `FML-STATUS` to `FOK`. On error, the system sets the `FML-STATUS` to a non-zero value.

Creating an FML Header File

In order to use an FML typed record in client programs or service subroutines, you must create an FML header file and specify it in the application `#include` statements.

To create an FML header file from a field table file, use the `mkfldhdr(1)` command. For example, to create a file called `myview.flds.h`, enter the following command:

```
mkfldhdr myview.flds
```

For `FML32` typed records, use the `mkfldhdr32` command.

[Listing 3-6](#) shows the `myview.flds.h` header file that is created by the `mkfldhdr` command.

Listing 3-6 myview.flds.h Header File

```

/*      fname      fldid      */
/*      -----      -----      */

#define  FLOAT1      ((FLDID)24686)  /* number: 110 type: float */
#define  DOUBLE1     ((FLDID)32879)  /* number: 111 type: double */
#define  LONG1       ((FLDID)8304)   /* number: 112 type: long  */
#define  SHORT1      ((FLDID)113)    /* number: 113 type: short */
#define  INT1        ((FLDID)8306)   /* number: 114 type: long  */
#define  DEC1        ((FLDID)41075)  /* number: 115 type: string */
#define  CHAR1       ((FLDID)16500)  /* number: 116 type: char  */
#define  STRING1     ((FLDID)41077)  /* number: 117 type: string */
#define  CARRAY1     ((FLDID)49270)  /* number: 118 type: carray */

```

Specify the new header file in the `#include` statement of your application. Once the header file is included, you can refer to fields by their symbolic names.

- [“Using a VIEW Typed Record” on page 3-7](#)
- [“Using an XML Typed Record” on page 3-20](#)
- `mkfldhdr`, `mkfldhdr32(1)` in the *Oracle Tuxedo Command Reference*

Using an XML Typed Record

XXML records enable Oracle Tuxedo applications to use XML for exchanging data within and between applications. Oracle Tuxedo applications can send and receive simple XML records, and route those records to the appropriate servers. All logic for dealing with XML documents, including parsing, resides in the application.

An XML document consists of:

- A sequence of characters that encode the text of a document
- A description of the logical structure of the document and information about that structure

Formatting and filtering for Events processing (which are supported when a `STRING` record type is used) are not supported for the XML record type. Therefore, the `_tmfilter` and `_tmformat` pointers in the record type switch for XML records are set to `LOW-VALUE`.

The XML parser in the Oracle Tuxedo system performs the following routines:

- Autodetection of character encodings
- Character code conversion
- Detection of element content and attribute values
- Data type conversion

Data-dependent routing is supported for XML records. The routing of an XML document can be based on element content, or on element type and an attribute value. The XML parser determines the character encoding being used; if the encoding differs from the native character sets (US-ASCII or EBCDIC) used in the Oracle Tuxedo configuration files (`UBBCONFIG` and `DMCONFIG`), the element and attribute names are converted to US-ASCII or EBCDIC.

Attributes configured for routing must be included in an XML document. If an attribute is configured as a routing criteria but it is not included in the XML document, routing processing fails.

The content of an element and the value of an attribute must conform to the syntax and semantics required for a routing field value. The user must also specify the type of the routing field value. XML supports only character data. If a range field is numeric, the content or value of that field is converted to a numeric value during routing processing.

Writing Clients

This topic includes the following sections:

- [Joining an Application](#)
- [Using Features of the TPINFDEF-REC Record](#)
- [Leaving the Application](#)
- [Building Clients](#)
- [Client Process Examples](#)

Joining an Application

Before an ATMI client can perform any service request, it must join the Oracle Tuxedo ATMI application, either explicitly or implicitly. Once the client has joined the application, it can initiate requests and receive replies.

A client joins an application explicitly by calling `TPINITIALIZE(3cbl)` with the following signature:

```
01 TPINFDEF-REC.  
   COPY TPINFDEF.  
01 USER-DATA-REC      PIC X(any-length).  
01 TPSTATUS-REC.  
   COPY TPSTATUS.  
CALL "TPINITIALIZE" USING TPINFDEF-REC USER-DATA-REC TPSTATUS-REC.
```

A client joins an application implicitly by issuing a service request (or any ATMI call) without first calling `TPINITIALIZE`. In this case, `TPINITIALIZE` is called by the Oracle Tuxedo system on behalf of the client with the `SPACES` parameter. The `TPINFDEF-REC` record is a special Oracle Tuxedo system typed record used by a client program to pass client identification and authentication information to the system when the client attempts to join the application. It is defined in a COBOL `COPY` file, as follows:

```
05 USRNAME          PIC X(30).
05 CLTNAME          PIC X(30).
05 PASSWD           PIC X(30).
05 GRPNAME          PIC X(30).
05 NOTIFICATION-FLAG PIC S9(9) COMP-5.
    88 TPU-SIG       VALUE 1.
    88 TPU-DIP       VALUE 2.
    88 TPU-IGN       VALUE 3.
05 ACCESS-FLAG      PIC S9(9) COMP-5.
    88 TPSA-FASTPATH VALUE 1.
    88 TPSA-PROTECTED VALUE 2.
05 DATALEN         PIC S9(9) COMP-5.
```

[Table 4-1](#) lists the fields that are defined in a COBOL `COPY` file.

Table 4-1 COBOL COPY File Fields

Field	Description
USRNAME	Name representing the caller. You may want to specify the value returned by the UNIX command <code>getuid(2)</code> within this field. The value of <code>USRNAME</code> may contain up to <code>MAXTIDENT</code> characters (which is defined as 30).
CLTNAME	Name of a client for which the semantics are application-defined. The value of <code>CLTNAME</code> may contain up to <code>MAXTIDENT</code> characters (which is defined as 30).
PASSWD	Application password in unencrypted format that is used by <code>TPINITIALIZE</code> for validation against the application password stored in the <code>TUXCONFIG</code> file. <code>PASSWD</code> is a string of up to <code>MAXTIDENT</code> characters.

Table 4-1 COBOL COPY File Fields

Field	Description
GRPNAME	Resource manager group name with which you want to associate the client. The client can access an XA-compliant resource manager as part of a global transaction. The GRPNAME can be a value up to MAXTIDENT characters (which is defined as 30). Currently, however, the GRPNAME must be passed as SPACES specifying that the client is not associated with a resource manager group and is in the default client group.
NOTIFICATION-FLAG	Notification mechanism and system access mode to be used. Refer to “Unsolicited Notification Handling” on page 4-5 for a list of valid values.
ACCESS-FLAG	System access mode used. Refer to “System Access Mode” on page 4-6 for a list of values.
DATALEN	Length of the application-specific data that will be sent to the authentication service. For native clients, it is not encoded by the system, but passed to the authentication service as provided by the client. For workstation clients, client authentication is handled by the system, and passed over the network in encrypted form.

The USERNAME and CLTNAME fields are associated with the client process when TPINITIALIZE is called. Both fields are used for both broadcast notification and the retrieval of administrative statistics.

- [TPINITIALIZE\(3cbl\)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference*

Using Features of the TPINFDEF-REC Record

The ATMI client must explicitly invoke TPINITIALIZE in order to take advantage of the following features of the TPINFDEF-REC record:

- [Client Naming](#)
- [Unsolicited Notification Handling](#)

- [System Access Mode](#)
- [Resource Manager Association](#)
- [Client Authentication](#)

Client Naming

When an ATMI client joins an application, the Oracle Tuxedo system assigns a unique client identifier to it. The identifier is passed to each service called by the client. It can also be used for unsolicited notification.

You can also assign unique client and usernames of up to 30 characters each, by passing them to `TPINITIALIZE` via the `TPINFDEF-REC` record. The Oracle Tuxedo system establishes a unique identifier for each process by combining the client and usernames associated with it, with the logical machine identifier (LMID) of the machine on which the process is running. You may choose a method for acquiring the values for these fields.

Note: If a process is executing outside the administrative domain of the application (that is, if it is running on a workstation connected to the administrative domain), the LMID of the machine used by the Workstation client to access the application is assigned.

Once a unique identifier for a client process is created:

- Client authentication can be implemented.
- Unsolicited messages can be sent to a specific client or to groups of clients via `TPNOTIFY` and `TPBROADCAST`.
- Detailed statistical information can be gathered via `tmadmin(1)`.

Refer to “Writing Event-based Clients and Servers” for information on sending and receiving unsolicited messages, and the *Oracle Tuxedo ATMI C Function Reference* for more information on `tmadmin(1)`.

[Figure 4-1](#) shows how names might be associated with clients accessing an application. In the example, the application uses the `cltname` field to indicate a job function.

Figure 4-1 Client Naming

Unsolicited Notification Handling

Unsolicited notification refers to any communication with an ATMI client that is not an expected response to a service request (or an error code). For example, an administrator may broadcast a message to indicate that the system will go down in five minutes.

A client can be notified of an unsolicited message in a number of ways. For example, some operating systems might send a signal to the client and interrupt its current processing. By default, the Oracle Tuxedo system checks for unsolicited messages each time an ATMI call is invoked. This approach, referred to as *dip-in*, is advantageous because it:

- Is supported on all platforms
- Does not interrupt the current processing

As some time may elapse between “dip-ins,” the application can call the `TPCHKUNSOL` call to check for any waiting unsolicited messages. Refer to [“Writing Event-based Clients and Servers”](#) in *Programming An Oracle Tuxedo ATMI Application Using C* for more information on the `TPCHKUNSOL` call.

When a client joins an application using `TPINITIALIZE`, it can control how to handle unsolicited notification messages by defining flags. For client notification, the possible values for `NOTIFICATION-FLAG` are defined in [Table 4-2](#).

Table 4-2 Client Notification Flags in a TPINFDEF-REC Record

Flag	Description
TPU_SIG	Select unsolicited notification by signals. This flag should be used only with single-threaded, single-context applications. The advantage of using this mode is immediate notification. The disadvantages include: <ul style="list-style-type: none">• The calling process must have the same <i>UID</i> as the sending process when you are running a native client. (Workstation clients do not have this limitation.)• TPU_SIG is not available on all platforms (specifically, it is not available on MS-DOS workstations). If you specify this flag but do not meet the system or environmental requirements, the flag is set to TPU_DIP and the event is logged.
TPU_DIP (default)	Select unsolicited notification by dip-in. In this case, the client can specify the name of the message handling routine using the TPSETUNSOL call, and check for waiting unsolicited messages using the TPCHKUNSOL call.
TPU_THREAD	Select THREAD notification in a separate thread. This flag is allowed only on platforms that support multithreading. If TPU_THREAD is specified on a platform that does not support multithreading, it is considered an invalid argument. As a result, an error is returned and TP-STATUS is set to TPEINVAL.
TPU_IGN	Ignore unsolicited notification.

Refer to [TPINITIALIZE\(3cbl\)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference* for more information on the TPINFDEF-REC flags.

System Access Mode

An application can access the Oracle Tuxedo system through either of two modes: protected or fastpath. The ATMI client can request a mode when it joins an application using `TPINITIALIZE`. To specify a mode, a client passes one of the following values in the `ACCESS-FLAG` field of the `TPINFDEF-REC` record to `TPINITIALIZE`.

Table 4-3 System Access Flags in a TPINFDEF-REC Record

Mode	Description
TPSA-PROTECTED	Allows ATMI calls within an application to access the Oracle Tuxedo system internal tables via shared memory, but protects shared memory against access by application code outside of the Oracle Tuxedo system libraries. Overrides the value in <code>UBBCONFIG</code> , except when <code>NO_OVERRIDE</code> is specified. Refer to <i>Setting Up an Oracle Tuxedo Application</i> for more information on <code>UBBCONFIG</code> .
TPSA-FASTPATH (default)	Allows ATMI calls within application code access to Oracle Tuxedo system internals via shared memory. Does not protect shared memory against access by application code outside of the Oracle Tuxedo system libraries. Overrides the value of <code>UBBCONFIG</code> except when <code>NO_OVERRIDE</code> is specified. Refer to <i>Setting Up an Oracle Tuxedo Application</i> for more information on <code>UBBCONFIG</code> .

Resource Manager Association

An application administrator can configure groups for servers associated with a resource manager, including servers that provide administrative processes for coordinating transactions. Refer to *Setting Up an Oracle Tuxedo Application* for information on defining groups.

When joining the application, a client can join a particular group by specifying the name of that group in the `grpname` field of `TPINFDEF-REC`.

Client Authentication

The Oracle Tuxedo system provides security at incremental levels, including operating system security, application password, user authentication, optional access control lists, mandatory access control lists, and link-level encryption. Refer to *Setting Up an Oracle Tuxedo Application* for information on setting security levels.

The application password security level requires every client to provide an application password when it joins the application. The administrator can set or change the application password and must provide it to valid users.

If this level of security is used, Oracle Tuxedo system-supplied client programs, such as `ud()`, prompt for the application password. (Refer to *Administering an Oracle Tuxedo Application at*

Run Time for more information on `ud`, `wud(1)`.) In turn, application-specific client programs must include code for obtaining the password from a user. The unencrypted password is placed in the `TPINFDEF-REC` record and evaluated when the client calls `TPINITIALIZE` to join the application.

Note: The password should not be displayed on the screen.

You can use `TPCHKAUTH(3cbl)` to determine:

- Whether the application requires any authentication
- If the application requires authentication, which of the following types of authentication is needed:
 - System authentication based on an application password
 - Application authentication based on an application password and user-specific information

Typically, a client should call `TPCHKAUTH` before `TPINITIALIZE` to identify any additional security information that must be provided during initialization.

Refer to *Using Security in CORBA Applications* for more information on security programming techniques.

Leaving the Application

Once all service requests have been issued and replies received, the ATMI client can leave the application using `TPTERM(3cbl)`. The `TPTERM` call signature is as follows:

```
01 TPSTATUS-REC .  
   COPY TPSTATUS .  
CALL "TPTERM" USING TPSTATUS-REC .
```

Building Clients

To build an executable ATMI client, compile your application with the Oracle Tuxedo system libraries and all other referenced files using the `buildclient(1)` command. Include the `-C` option to indicate that you are compiling a COBOL program. Use the following syntax for the `buildclient` command:

```
buildclient -C filename.cbl -o filename -f filenames -l filenames
```

[Table 4-4](#) describes the options to the `buildclient` command.

Table 4-4 buildclient Options

This Option or Argument .	Allows You to Specify . . .
..	
<i>filename.cbl</i>	The COBOL application to be compiled.
<i>-o filename</i>	The executable output file. The default name for the output file is <i>a.out</i> .
<i>-f filenames</i>	A list of files that are to be link edited before the Oracle Tuxedo system libraries are link edited. You can specify <i>-f</i> more than once on the command line, and you can include multiple filenames for each occurrence of <i>-f</i> . If you specify a COBOL program file (<i>file.cbl</i>), it is compiled before it is linked. You can specify other object files (<i>file.o</i>) separately, or in groups in an archive file (<i>file.a</i>).
<i>-l filenames</i>	A list of files that are to be link edited after the Oracle Tuxedo system libraries are link edited. You can specify <i>-l</i> more than once on the command line, and you can include multiple filenames for each occurrence of <i>-l</i> . If you specify a COBOL program file (<i>file.cbl</i>), it is compiled before it is linked. You can specify other object files (<i>file.o</i>) separately, or in groups in an archive file (<i>file.a</i>).
<i>-r</i>	The resource manager has access to libraries that should be link edited with the executable server. The application administrator is responsible for predefining all valid resource manager information in the <i>\$TUXDIR/updataobj/RM</i> file using the <i>buildtms(1)</i> command. Only one resource manager can be specified. Refer to <i>Setting Up an Oracle Tuxedo Application</i> for more information.

Notes: The Oracle Tuxedo libraries are linked in automatically; you do not need to specify any Oracle Tuxedo libraries on the command line.

Link editing must be done by running the `buildclient` command.

The order in which you specify the library files to be link edited is significant: it depends on the order in which functions are called in the code, and which libraries contain references to those functions.

By default, the `buildclient` command invokes the UNIX `cc` command. You can set the `ALTCC` and `ALTCFLAGS` environment variables to specify an alternative compile command, and to set flags for the compile and link-edit phases, respectively. By default, `ALTCC` is set to `cobcc`, which uses the MicroFocus Net Express compiler. To use Fujitsu's NetCOBOL `ALTCC` must be set, even on a Windows system. You must set `ALTCC=cobcc85` for NetCOBOL. For more information, refer to [“Setting Environment Variables”](#) in *Programming An Oracle Tuxedo ATMI Application Using C*.

Note: On a Windows system, the `ALTCC` and `ALTCFLAGS` environment variables are not applicable; setting them will produce unexpected results. You must compile your application by first using a COBOL compiler, and then passing the resulting object file to the `buildclient` command. For example:

```
buildclient -C -o audit -f audit.o
```

The following example command line compiles a COBOL program called `audit.cbl` and generates an executable file named `audit`.

```
buildclient -C -o audit -f audit.cbl
```

See Also

- [“Building Servers”](#) in *Programming An Oracle Tuxedo ATMI Application Using C*
- [buildclient\(1\)](#) in the *Oracle Tuxedo Command Reference*

Client Process Examples

The following pseudo-code in [Listing 4-1](#) shows how a typical ATMI client process works from the time at which it joins an application to the time at which it leaves the application.

Listing 4-1 Typical Client Process Paradigm

```
. . .
Check level of security
    CALL TPSETUNSOL to name your handler routine for TPU-DIP
    get USRNAME, CLTNAME
    prompt for application PASSWD
    SET TPU-DIP TO TRUE.
    CALL "TPINITIALIZE" USING TPINFDEF-REC
```

```

                                USER-DATA-REC
                                TPSTATUS-REC.
    IF NOT TPOK
        error processing
    . . .
    make service call
    receive the reply
    check for unsolicited messages
    . . .
    CALL "TPTERM" USING TPSTATUS-REC.
    IF NOT TPOK
        error processing
    . . .
    EXIT PROGRAM.

```

In this example, TPINITIALIZE takes three arguments:

- TPINFDEF-REC, a structure defined in the COBOL COPY file
- User data (USER-DATA-REC)
- TPSTATUS-REC, a status structure defined in the COBOL COPY file

Both TPINITIALIZE and TPTERM return [TPOK] in TP-STATUS IN TPSTATUS-REC upon success. If either command encounters an error, the command fails and sets TP-STATUS to a value that indicates the nature of the error. TPSTATUS-REC is defined in a COBOL COPY file. Refer to [“Managing Errors”](#) in *Programming An Oracle Tuxedo ATMI Application Using C* for possible TP-STATUS values. Refer to [“Introduction to the COBOL Application-Transaction Monitor Interface”](#) in the *Oracle Tuxedo ATMI COBOL Function Reference* for a complete list of error codes that can be returned for each of the ATMI calls.

The following example illustrates how to use the TPINITIALIZE and TPTERM routines. This example is borrowed from, bankapp, the sample banking application that is provided with the Oracle Tuxedo system.

. . .
*****
*Leave Application
*****
CALL "TPTERM" USING TPSTATUS-REC.
IF NOT TPOK
        MOVE "TPTERM FAILED" TO LOGMSG-TEXT
        PERFORM DO-USERLOG.
EXIT-PROGRAM.
STOP RUN.
*****
* Log messages to the userlog
*****
DO-USERLOG.
CALL "USERLOG" USING LOGMSG
        LOGMSG-LEN
        TPSTATUS-REC.

```

The previous example shows the client process attempting to join the application with a call to TPINITIALIZE. If an error is encountered, a message is written to the central event log via a call to USERLOG.

Writing Servers

This topic includes the following sections:

- [Oracle Tuxedo System Controlling Program](#)
- [System-supplied Server and Services](#)
- [Guidelines for Writing Servers](#)
- [Defining a Service](#)
- [Terminating a Service Routine](#)
- [Advertising and Unadvertising Services](#)
- [Building Servers](#)

Oracle Tuxedo System Controlling Program

To facilitate the development of ATMI servers, the Oracle Tuxedo system provides a predefined controlling program for server load modules. When you execute the `buildserver -c` command, the controlling program is automatically included as part of the server.

Note: The controlling program that the system provides is a closed abstraction; you cannot modify it.

In addition to joining and exiting from an application, the predefined controlling program accomplishes the following tasks on behalf of the server.

- Executes the process ignoring any hangups (that is, it ignores the `SIGHUP` signal).

- Initiates the cleanup process on receipt of the standard operating system software termination signal (SIGTERM). The server is shut down and must be rebooted if needed again.
- Attaches to shared memory for bulletin board services.
- Creates a message queue for the process.
- Advertises the initial services to be offered by the server. The initial services are either all the services link edited with the predefined controlling program, or a subset specified by the Oracle Tuxedo system administrator in the configuration file.
- Processes command-line arguments up to the double dash (--), which indicates the end of system-recognized arguments.
- Calls the routine `TPSVRINIT` to process any command-line arguments listed after the double dash (--) and optionally to open the resource manager. These command-line arguments are used for application-specific initialization.
- Until ordered to halt, checks its request queue for service request messages.
- When a service request message arrives on the request queue, `main()` performs the following tasks until ordered to halt:
 - If the `-r` option is specified, records the starting time of the service request.
 - Updates the bulletin board to indicate that the server is `BUSY`.
 - Dispatches the service; that is, calls the service subroutine.
- When the service returns from processing its input, `main()` performs the following tasks until ordered to halt:
 - If the `-r` option is specified, records the ending time of the service request.
 - Updates statistics.
 - Updates the bulletin board to indicate that the server is `IDLE`; that is, that the server is ready for work.
 - Checks its queue for the next service request.
- When the server is required to halt, calls `TPSVRDONE` to perform any required shutdown operations.

As indicated above, the `main()` routine handles all of the details associated with joining and exiting from an application, managing records and transactions, and handling communication.

Note: Because the system-supplied controlling program accomplishes the work of joining and leaving the application, you should not include calls to the `TPINITIALIZE` or `TPTERM` routine in your code. If you do, the routine encounters an error and returns `TPEPROTO` in `TP-STATUS`. For more information on the `TPINITIALIZE` or `TPTERM` routine, refer to “Writing Clients” in *Programming Oracle Tuxedo ATMI Applications Using C*.

System-supplied Server and Services

The controlling program provides one system-supplied ATMI server, `AUTHSVR`, and two subroutines, `TPSVRINIT` and `TPSVRDONE`. The default versions of all three, which are described in the following sections, can be modified to suit your application.

Notes: If you want to write your own versions of `TPSVRINIT` and `TPSVRDONE`, remember that the default versions of these two routines call `tx_open()` and `tx_close()`, respectively. If you write a new version of `TPSVRINIT` that calls `tpopen()` rather than `tx_open()`, you should also write a new version of `TPSVRDONE` that calls `tpclose()`. In other words, both routines in an open/close pair must belong to the same set.

System-supplied Server: `AUTHSVR()`

You can use the `AUTHSVR(5)` server to provide individual client authentication for an application. The `TPINITIALIZE` routine calls this server when the level of security for the application is `TPAPPAUTH`, `USER_AUTH`, `ACL`, or `MANDATORY_ACL`.

The service in `AUTHSVR` looks in the `USER-DATA-REC` record for a user password (not to be confused with the application password specified in the `PASSWD` field of the `TPINFDEF-REC` record). By default, the system takes the string in `data` and searches for a matching string in the `/etc/passwd` file.

When called by a native-site client, `TPINITIALIZE` forwards the `USER-DATA-REC` record as it is received. This means that if the application requires the password to be encrypted, the client program must be coded accordingly.

When called by a Workstation client, `TPINITIALIZE` encrypts the data before sending it across the network.

System-supplied Services: `TPSVRINIT` Routine

When a server is booted, the Oracle Tuxedo system controlling program calls `TPSVRINIT(3cb1)` during its initialization phase, before handling any service requests.

If an application does not provide a custom version of this routine within the server, the system uses the default routine provided by the controlling program, which opens the resource manager and logs an entry in the central event log indicating that the server has successfully started. The central user log is an automatically generated file to which processes can write messages by calling the `USERLOG(3cb1)` routine. Refer to “[Managing Errors](#)” in *Programming Oracle Tuxedo ATMI Applications Using C* for more information on the central event log.

You can use the `TPSVRINIT` routine for any initialization processes that might be required by an application, such as the following:

- Receiving command-line options
- Opening a database

The following sections provide code samples showing how these initialization tasks are performed through calls to `TPSVRINIT`. Although it is not illustrated in the following examples, message exchanges can also be performed within this routine. However, `TPSVRINIT` fails if it returns with asynchronous replies pending. In this case, the replies are ignored by the Oracle Tuxedo system, and the server exits gracefully.

You can also use the `TPSVRINIT` routine to start and complete transactions, as described in “[Managing Errors](#)” in *Programming Oracle Tuxedo ATMI Applications Using C*.

Use the following signature to call the `TPSVRINIT` routine

```
LINKAGE SECTION.
01 CMD-LINE.
    05 ARGC          PIC 9(4) COMP-5.
    05 ARGV.
        10 ARGS PIC X OCCURS 0 TO 9999 DEPENDING ON ARGC.
01 TPSTATUS-REC.
    COPY TPSTATUS.
PROCEDURE DIVISION USING CMD-LINE TPSTATUS-REC.
* User code
EXIT PROGRAM.
```

Receiving Command-line Options

When a server is booted, its first task is to read the server options specified in the configuration file. The options are passed through `ARGC`, which contains the number of arguments, and `ARGV`, which contains the arguments separated by a single `SPACE` character. The predefined controlling program then calls `TPSVRINIT`.

The following code example shows how the TPSVRINIT routine is used to receive command-line options.

Listing 5-1 Receiving Command-line Options in TPSVRINIT

```

*
. . . INSPECT the ARGV line and process arguments
IF arguments are invalid
    SET TPEINVAL IN SERVER-INIT-STATUS TO TRUE.
ELSE arguments are OK continue
    SET TPOK IN SERVER-INIT-STATUS TO TRUE.

```

```

*
EXIT PROGRAM.

```

Opening a Resource Manager

The following example illustrates another common use of TPSVRINIT: opening a resource manager. The Oracle Tuxedo system provides routines to open a resource manager, `TPOPEN(3cbl)` and `TXOPEN(3cbl)`. It also provides the complementary routines, `TPCLOSE(3cbl)` and `TXCLOSE(3cbl)`. Applications that use these routines to open and close their resource managers are portable in this respect. They work by accessing the resource manager instance-specific information that is available in the configuration file.

These routine calls are optional and can be used in place of the resource manager specific calls that are sometimes part of the Data Manipulation Language (DML) if the resource manager is a database. Note the use of the `USERLOG(3cbl)` routine to write to the central event log.

Note: To create an initialization function that both receives command-line options and opens a database, combine the following example with the previous example.

Listing 5-2 Opening a Resource Manager in TPSVRINIT

```

IDENTIFICATION DIVISION.
PROGRAM-ID. TPSVRINIT.
ENVIRONMENT DIVISION.
CONFIGURATION SECTION.
SOURCE-COMPUTER.  USL-486.
OBJECT-COMPUTER.  USL-486.
*
DATA DIVISION.
WORKING-STORAGE SECTION.
    01 TPSTATUS-REC.
        COPY TPSTATUS.
    01 LOGMSG          PIC X(50).
    01 LOGMSG-LEN      PIC S9(9) COMP-5.
*
LINKAGE SECTION.
    01 CMD-LINE.

```

```

05 ARGV PIC 9(4) COMP-5.
05 ARGV.
10 ARGS PIC X OCCURS 0 TO 9999 DEPENDING ON ARGV.
01 SERVER-INIT-STATUS.
COPY TPSTATUS.
*
PROCEDURE DIVISION USING CMD-LINE SERVER-INIT-STATUS.
A-START.
. . . INSPECT the ARGV line and process arguments
IF arguments are invalid
MOVE "Invalid Arguments Passed" TO LOGMSG
PERFORM EXIT-NOW.
ELSE arguments are OK continue

CALL "TPOPEN" USING TPSTATUS-REC.
IF NOT TPOK
MOVE "TPOPEN Failed" TO LOGMSG
ELSE IF TPESYSTEM
MOVE "System /T error has occurred" TO LOGMSG
ELSE IF TPEOS
MOVE "An Operating System error has occurred" TO LOGMSG
ELSE IF TPEPROTO
MOVE "TPOPEN was called in an improper Context" TO LOGMSG
ELSE IF TPERMERR
MOVE "Resource manager Failed to Open" TO LOGMSG
PERFORM EXIT-NOW.
SET TPOK IN SERVER-INIT-STATUS TO TRUE.
EXIT PROGRAM.
EXIT-NOW.
SET TPEINVAL IN SERVER-INIT-STATUS TO TRUE
MOVE 50 LOGMSG-LEN.
CALL "USERLOG" USING LOGMSG
LOGMSG-LEN
TPSTATUS-REC.
EXIT PROGRAM.

```

To guard against errors that may occur during initialization, TPSVRINIT can be coded to allow the server to exit gracefully before starting to process service requests.

System-supplied Services: TPSVRDONE Routine

The TPSVRDONE routine calls TPCLOSE to close the resource manager, similarly to the way TPSVRINIT calls TPOPEN to open it.

Use the following signature to call the TPSVRDONE routine:

```
01 TPSTATUS-REC.  
   COPY TPSTATUS.  
PROCEDURE DIVISION.  
* User code  
   EXIT PROGRAM.
```

The following example illustrates how to use the TPSVRDONE routine to close a resource manager and exit gracefully.

Listing 5-3 Closing a Resource Manager with TPSVRDONE

    MOVE "System /T error has occurred" TO LOGMSG
ELSE IF TPEOS
    MOVE "An Operating System error has occurred" TO LOGMSG
ELSE IF TPEPROTO
    MOVE "TPCLOSE was called in an improper Context" TO LOGMSG
ELSE IF TPERMERR
    MOVE "Resource manager Failed to Open" TO LOGMSG
    PERFORM EXIT-NOW.
SET TPOK IN SERVER-DONE-STATUS TO TRUE.
EXIT PROGRAM.
EXIT-NOW.
SET TPEINVAL IN SERVER-DONE-STATUS TO TRUE
MOVE 50 LOGMSG-LEN.
CALL "USERLOG" USING LOGMSG
                        LOGMSG-LEN
                        TPSTATUS-REC.
EXIT PROGRAM.

```

Guidelines for Writing Servers

Because the communication details are handled by the Oracle Tuxedo system controlling program, you can concentrate on the application service logic rather than communication implementation. For compatibility with the system-supplied controlling program, however, application services must adhere to certain conventions. These conventions are referred to, collectively, as the service template for coding service routines. They are summarized in the following list.

- A request/response service can receive only one request at a time and can send only one reply.
- When processing a request, a request/response service works only on that request. It can accept another only after it has either sent a reply to the requester or forwarded the request to another service for additional processing.
- Service routines must terminate by calling either the TPRETURN or TPFORWAR routine.

- When communicating with another server via `TPACALL`, the initiating service must either wait for all outstanding replies or invalidate them with `TPCANCEL` before calling `TPRETURN` or `TPFORWAR`.

Defining a Service

When writing a service routine, you must call the [TPSVCSTART\(3cbl\)](#) routine before any others. This routine is used to retrieve the service's parameters and data. Use the following signature to call the TPSVCSTART routine

```
01 TPSVCDEF-REC.
   COPY TPSVCDEF.
01 TPTYPE-REC.
   COPY TPTYPE.
01 DATA-REC.
   COPY User Data.
01 TPSTATUS-REC.
   COPY TPSTATUS.
CALL "TPSVCSTART" USING TPSVCDEF-REC TPTYPE-REC DATA-REC TPSTATUS-REC.
```

The service information data structure is defined as TPSVCDEF in the COBOL COPY file. It includes the following members:

```
05 COMM-HANDLE          PIC S9(9) COMP-5.
05 TPBLOCK-FLAG         PIC S9(9) COMP-5.
    88 TPBLOCK          VALUE 0.
    88 TPNOBLOCK        VALUE 1.
05 TPTRAN-FLAG          PIC S9(9) COMP-5.
    88 TPTRAN           VALUE 0.
    88 TPNOTRAN         VALUE 1.
05 TPREPLY-FLAG         PIC S9(9) COMP-5.
    88 TPREPLY          VALUE 0.
    88 TPNOREPLY        VALUE 1.
05 TPACK-FLAG           PIC S9(9) COMP-5 REDEFINES TPREPLY-FLAG.
    88 TPNOACK          VALUE 0.
    88 TPACK            VALUE 1.
05 TPTIME-FLAG          PIC S9(9) COMP-5.
    88 TPTIME           VALUE 0.
    88 TPNOTIME         VALUE 1.
05 TPSIGRSTRT-FLAG      PIC S9(9) COMP-5.
    88 TPNOSIGRSTRT     VALUE 0.
    88 TPSIGRSTRT       VALUE 1.
05 TPGETANY-FLAG        PIC S9(9) COMP-5.
    88 TPGETHANDLE      VALUE 0.
    88 TPGETANY         VALUE 1.
```

```

05 TPSENDRECV-FLAG      PIC S9(9) COMP-5.
    88 TSENDONLY        VALUE 0.
    88 TPRECVONLY       VALUE 1.
05 TPNOCHANGE-FLAG      PIC S9(9) COMP-5.
    88 TPCHANGE         VALUE 0.
    88 TPNOCHANGE       VALUE 1.
05 TPSERVICETYPE-FLAG   PIC S9(9) COMP-5.
    88 TPREQRSP         VALUE 0.
    88 TPCONV           VALUE 1.
*
05 APPKEY                PIC S9(9) COMP-5.
05 CLIENTID OCCURS 4 TIMES PIC S9(9) COMP-5.
05 SERVICE-NAME          PIC X(127).

```

The following table describes the members of a TPSVCDEF data structure.

Table 5-1 TPSVCDEF Data Structure

Field	Description
COMM-HANDLE	Specifies, to the service routine, the communication handle used by the requesting process to invoke the service.
SETTINGS (TPBLOCK-FLAG TPTRAN-FLAG, etc.)	Miscellaneous settings that control server characteristics. For more information on the settings, refer to the <i>Oracle Tuxedo ATMI COBOL Function Reference</i> .
APPKEY	Reserved for use by the application. If application-specific authentication is part of your design, the application-specific authentication server, which is called at the time a client joins the application, should return a client authentication key, as well as a success or failure indication. The Oracle Tuxedo system holds the APPKEY on behalf of the client and passes the information to subsequent service requests in this field. By the time the APPKEY is passed to the service, the client has already been authenticated. However, the APPKEY field can be used within the service to identify the user invoking the service or some other parameters associated with the user.
CLIENTID	Identifier of the client that originates a request.
SERVICE-NAME	Name of the service routine used by the requesting process to invoke the service.

For a description of the TPTYPE-REC data structure, refer to [“Defining Typed Records” on page 3-6](#).

You must code the service in such a way that when it accesses the request data to be placed in DATA-REC, it expects the data to be in a record of the type defined for the service in the configuration file. Upon successful return, DATA-REC contains the data received and LEN contains the actual number of bytes moved.

The following sample listing shows a typical service definition.

```

In the preceding example, the request record on the client side was originally sent with `REC-TYPE` set to `VIEW` and the `SUB-TYPE` set to `cust`. The `BUYSR` service is defined in the configuration file as a service that knows about the `VIEW` typed record. `BUYSR` retrieves the data record by accessing the `CUST-REC` record. The consistency level of the transaction is specified after this record is retrieved but before the first database access is made. For more details on transaction consistency levels, refer to [“Writing Global Transactions”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

Note: The TPGPRIO and TPSPRIO routines, used for getting and setting priorities, respectively, are described in detail in [“Setting and Getting Message Priorities”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

The example code in this section shows how a service called PRINTER tests the priority level of the request just received using the TPGPRIO routine. Then, based on the priority level, the application routes the print job to the appropriate destination printer RNAME.

Next, the contents of INPUT-REC are sent to the printer. The application queries TPSVCDEF-REC to determine whether a reply is expected. If so, it returns the name of the destination printer to the client. For more information on the TPRETURN routine, refer to [“Terminating a Service Routine”](#) on page 5-19.

Terminating a Service Routine

The [TPRETURN\(3cbl\)](#), [TPCANCEL\(3cbl\)](#), and [TPFORWAR\(3cbl\)](#) routines specify that a service routine has completed with one of the following actions:

- [TPRETURN](#) sends a reply to the calling client.
- [TPCANCEL](#) cancels the current request.
- [TPFORWAR](#) forwards a request to another service for further processing.

Sending Replies

The [TPRETURN\(3cbl\)](#) and [TPFORWAR\(3cbl\)](#) calls are COBOL copy files that contain `EXIT` statements to mark the end of a service routine and send a message to the requester or forward the request to another service, respectively. Use the following signature to call the [TPRETURN](#) routine:

```

01 TPSVCRET-REC.
   COPY TPSVCRET.
01 TPTYPE-REC.
   COPY TPTYPE.
01 DATA-REC.
   COPY User Data.
01 TPSTATUS-REC.

```

```

COPY TPSTATUS.
COPY TPRETURN REPLACING TPSVCRET-REC BY TPSVCRET-REC
      TPTYPE-REC BY TPTYPE-REC
      DATA-REC BY DATA-REC
      TPSTATUS-REC BY TPSTATUS-REC.

```

Note: You must use `COPY` here instead of `CALL` to ensure that the `EXIT` statement is called properly, and the COBOL service routine returns control to the Oracle Tuxedo system.

The following listing provides the `TPSVCRET-REC` record signature:

```

05 TPRETURN-VAL      PIC S9(9) COMP-5.
   88 TPSUCCESS      VALUE 0.
   88 TPFALL          VALUE 1.
   88 TPFALL          VALUE 2.
05 APPL-CODE         PIC S9(9) COMP-5.

```

[Table 5-2](#) describes the members of a TPSVCRET-REC data structure.

Table 5-2 TPSVCRET-REC Data Structure Members

Member	Description
TP-RETURN-VAL	<p>Indicates whether or not the service has completed successfully on an application-level. The value is an integer that is represented by a symbolic name. Valid settings include:</p> <ul style="list-style-type: none"> TPSUCCESS—the calling routine succeeded. The routine stores the reply message in the caller's record. If there is a reply message, it is in the caller's record. TPFAIL (default)—the service terminated unsuccessfully. The routine reports an error message to the client process waiting for the reply. In this case, the client's TPCALL or TPGETRPLY routine call fails and the system sets the TP-STATUS variable to TPESVCFAIL to indicate an application-defined failure. If a reply message was expected, it is available in the caller's record. TPEXIT—the service terminated unsuccessfully. The routine reports an error message to the client process waiting for the reply, and exits. <p>For a description of the effect that the value of this argument has on global transactions, refer to “Writing Global Transactions” in <i>Programming Oracle Tuxedo ATMI Applications Using C</i>.</p>
APPLC-CODE	<p>Returns an application-defined return code to the caller. The client can access the value returned in APPLC-CODE by querying APPL-RETURN-CODE IN TPSTATUS-REC. The routine returns this code regardless of success or failure.</p>

Refer to [“Defining a Service” on page 5-11](#) for a description of the TPTYPE-REC record.

The primary function of a service routine is to process a request and return a reply to a client process. It is not necessary, however, for a single service to do all the work required to perform the requested function. A service can act as a requester and pass a request call to another service the same way a client issues the original request: through calls to TPCALL or TPACALL.

Note: The TPCALL and TPACALL routines are described in detail in [“Writing Request/Response Clients and Servers”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

When `TPRETURN` is called, control always returns to the controlling program. If a service has sent requests with asynchronous replies, it must receive all expected replies or invalidate them with `TPCANCEL` before returning control to the controlling program. Otherwise, the outstanding replies are automatically dropped when they are received by the Oracle Tuxedo system controlling program, and an error is returned to the caller.

If the client invokes the service with `TPCALL`, after a successful call to `TPRETURN`, the reply message is available in the `O-DATA-REC` record. If `TPACALL` is used to send the request, and `TPRETURN` returns successfully, the reply message is available in the `DATA-REC` record of `TPGETRPLY`.

If a reply is expected and `TPRETURN` encounters errors while processing its arguments, it sends a failed message to the calling process. The caller detects the error by checking the value placed in `TP-STATUS`. In the case of failed messages, the system sets the `TP-STATUS` to `TPESVCERR`. This situation takes precedence over the value of `APPL-RETURN-CODE` in `TPSTATUS-REC`. If this type of error occurs, no reply data is returned, and both the contents and length of the caller's output record remain unchanged.

If `TPRETURN` returns a message in a record of an unknown type or a record that is not allowed by the caller (that is, if the call is made with `TPNOCHANGE`), the system returns `TPEOTYPE` in `TP-STATUS`. In this case, application success or failure cannot be determined, and the contents and length of the output record remain unchanged.

The value returned in `APPL-RETURN-CODE` in `TPSTATUS-REC` is not relevant if the `TPRETURN` routine is invoked and a timeout occurs for the call waiting for the reply. This situation takes precedence over all others in determining the value that is returned in `TP-STATUS`. In this case, `TP-STATUS` is set to `TPETIME` and the reply data is not sent, leaving the contents and length of the caller's reply record unchanged. There are two types of timeouts in the Oracle Tuxedo system: blocking and transaction timeouts (discussed in [“Writing Global Transactions”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*).

The example code in this section shows the `TRANSFER` service that is part of the `XFER` server. Basically, the `TRANSFER` service makes synchronous calls to the `WITHDRAWAL` and `DEPOSIT` services. It allocates a separate record for the reply message since it must use the request record for the calls to both the `WITHDRAWAL` and the `DEPOSIT` services. If the call to `WITHDRAWAL` fails, the service writes the message `cannot withdraw` on the status line of the form and sets `TP-RETURN-VAL` in `TPSVCRET-REC` of the `TPRETURN` routine to `TPFAIL`. If the call succeeds, the debit balance is retrieved from the reply record.

Note: In the following example, the application moves the identifier for the “destination account” (which is retrieved from the `cr_id` variable) to the zeroth occurrence of the

ACCOUNT_ID field in the `transf` fielded record. This move is necessary because this occurrence of the field in an `FML` record is used for data-dependent routing. Refer to *Setting Up an Oracle Tuxedo Application* for more information.

A similar scenario is followed for the call to `DEPOSIT`. On success, the service sets the `TP-RETURN-VAL` IN `TPSVCRET-REC` to `TPSUCCESS`, returning the pertinent account information to the status line.

Invalidating Descriptors

If a service calling `TPGETRPLY` (described in detail in [“Writing Request/Response Clients and Servers”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*) fails with `TPETIME` and decides to cancel the request, it can invalidate the descriptor with a call to `TPCANCEL(3cb1)`. If a reply subsequently arrives, it is silently discarded.

`TPCANCEL` cannot be used for transaction replies (that is, for replies to requests made without the `TPNOTTRAN` flag set). Within a transaction, `TPABORT(3cb1)` does the same job of invalidating the transaction call descriptor.

[Listing 5-7](#) shows how to invalidate a reply after timing out.

Listing 5-7 Invalidating a Reply After Timing Out

```
. . . Set up parameters to TPACALL
SET TPNOTRAN TO TRUE.
CALL "TPACALL" USING TPSVCDEF-REC
                    TPTYPE-REC

                    TPTYPE-REC BY TPTYPE-REC
                    DATA-REC BY DEBIT-REC
                    TPSTATUS-REC BY TPSTATUS-REC.
```

Forwarding Requests

The [TPFORWAR\(3cb1\)](#) routine allows a service to forward a request to another service for further processing.

Use the following signature to call the TPFORWAR routine:

```
01 TPSVCDEF-REC.
   COPY TPSVCDEF.
01 TPTYPE-REC.
   COPY TPTYPE.
```

```

01 DATA-REC.
   COPY User Data.
01 TPSTATUS-REC.
   COPY TPSTATUS.
COPY TPFORWAR REPLACING TPSVCDEF-REC BY TPSVCDEF-REC
      TPTYPE-REC BY TPTYPE-REC
      DATA-REC BY DATA-REC
      TPSTATUS-REC BY TPSTATUS-REC.

```

For descriptions of the TPSVCDEF-REC and TPTYPE-REC records, refer to [“Defining a Service” on page 5-11](#).

The functionality of TPFORWAR differs from a service call: a service that forwards a request does not expect a reply. The responsibility for providing the reply is passed to the service to which the request has been forwarded. The latter service sends the reply to the process that originated the request. It becomes the responsibility of the last server in the forward chain to send the reply to the originating client by invoking TPRETURN.

[Figure 5-1](#) shows one possible sequence of events when a request is forwarded from one service to another. Here a client initiates a request using the TPCALL routine and the last service in the chain (SVC_C) provides a reply using the TPRETURN routine.

Figure 5-1 Forwarding a Request

Service routines can forward requests at specified priorities in the same manner that client processes send requests, by using the TPSPRIO routine.

When a process calls `TPFORWAR`, the system that supplied the controlling program regains control, and the server process is free to do more work.

Note: If a server process is acting as a client and a reply is expected, the server is not allowed to request services from itself. If the only available instance of the desired service is offered by the server process making the request, the call fails, indicating that a recursive call cannot be made. However, if a service routine sends a request (to itself) with the `TPNOREPLY` communication flag set, or if it forwards the request, the call does not fail because the service is not waiting for itself.

Calling `TPFORWAR` can be used to indicate success up to that point in processing the request. If no application errors have been detected, you can invoke `TPFORWAR`, otherwise, you can call `TPRETURN` with `TP-RETURN-VAL IN TPSVCRET-REC` set to `TPFAIL`.

The following example illustrates how the service sends its data record to the `DEPOSIT` service by calling `TPFORWAR`. If the new account is added successfully, the branch record is updated to reflect the new account, and the data record is forwarded to the `DEPOSIT` service. On failure, `TPRETURN` is called with `TP-RETURN-VAL IN TPSVCRET-REC` set to `TPFAIL` and the failure is reported on the status line of the form.

Listing 5-8 How to Use `TPFORWAR`

```

. . .

```

Advertising and Unadvertising Services

When a server is booted, it advertises the services it offers based on the values specified for the `CLOPT` parameter in the configuration file.

Note: The services that a server may advertise are initially defined when the `buildserver` command is executed. The `-s` option allows a comma-separated list of services to be specified. It also allows you to specify a routine with a name that differs from that of the advertised service that is to be called to process the service request. Refer to the `buildserver(1)` in the *Oracle Tuxedo Command Reference* for more information.

The default specification calls for the server to advertise all services with which it was built. Refer to the `UBBCONFIG(5)` or `servopts(5)` reference page in the *File Formats, Data Descriptions, MIBs, and System Processes Reference* for more information.

Because an advertised service uses a service table entry in the bulletin board, and can therefore be resource-expensive, an application may boot its servers in such a way that only a subset of the services offered are available. To limit the services available in an application, define the `CLOPT` parameter, within the appropriate entry in the `SERVERS` section of the configuration file, to include the desired services in a comma-separated list following the `-s` option. The `-s` option also allows you to specify a routine with a name other than that of the advertised service to be called to process the request. Refer to the `servopts(5)` reference page in the *File Formats, Data Descriptions, MIBs, and System Processes Reference* for more information.

An Oracle Tuxedo application administrator can use the `advertise` and `unadvertise` commands of `tmadmin(1)` to control the services offered by servers. The `TPADVERTISE` and `TPUNADVERTISE` routines enable you to dynamically control the advertisement of a service in a request/response or conversational server. The service to be advertised (or unadvertised) must be available within the same server as the service making the request.

Advertising Services

Use the following signature to call the [TPADVERTISE\(3cbl\)](#) routine:

```
01 SERVICE-NAME          PIC X(127) .
01 PROGRAM-NAME          PIC X(32) .
01 TPSTATUS-REC .
    COPY TPSTATUS .
CALL "TPADVERTISE" USING SERVICE-NAME PROGRAM-NAME TPSTATUS-REC .
```

[Table 5-3](#) describes the members of a TPADVERTISE data structure.

Table 5-3 TPADVERTISE Data Structure Members

Member	Description
SERVICE-NAME	Name of the service to be advertised. The service name must be a character string of up to 127 characters. Names longer than 127 characters are truncated. The SPACES string is not a valid value. If it is specified, an error (TPEINVAL) results.
PROGRAM-NAME	Oracle Tuxedo system routine that is called to perform a service. Frequently, this name is the same as the name of the service. The SPACES string is not a valid value. If it is specified, an error results.

Unadvertising Services

The [TPUNADVERTISE\(3cbl\)](#) routine removes the name of a service from the service table of the bulletin board so that the service is no longer advertised.

Use the following signature for the TPUNADVERTISE routine:

```
01 SERVICE-NAME          PIC X(127) .
01 TPSTATUS-REC .
    COPY TPSTATUS .
CALL "TPUNADVERTISE" USING SERVICE-NAME TPSTATUS-REC .
```

The TPUNADVERTISE data structure contains one member, which is described in [Table 5-4](#).

Table 5-4 TPUNADVERTISE Data Structure Member

Member	Description
SERVICE-NAME	Name of the service to be advertised. The service name must be a character string of up to 127 characters. Names longer than 127 characters are truncated. The SPACES string is not a valid value. If it is specified, an error (TPEINVAL) results.

Example: Dynamic Advertising and Unadvertising of a Service

The following example shows how to use the TPADVERTISE routine. In this example, a server called TLR is programmed to offer only the service called TLRINIT when booted. After some initialization, TLRINIT advertises two services called DEPOSIT and WITHDRAW. Both are performed by the TLRFUNCS routine, and both are built into the TLR server.

After advertising DEPOSIT and WITHDRAW, TLRINIT unadvertises itself.

Listing 5-9 Dynamic Advertising and Unadvertising

```

. . .
*****
* Advertise DEPOSIT service to be processed by
* routine TLRFUNCS
*****
      MOVE "DEPOSIT" TO SERVICE-NAME.
      MOVE "TLRFUNCS" TO PROGRAM-NAME.

          error processing
*****
* Advertise WITHDRAW service to be processed by
* the same routine TLRFUNCS
*****

```

```

MOVE "WITHDRAW" TO SERVICE-NAME.
MOVE "TLRFUNCS" TO PROGRAM-NAME.
CALL "TPADVERTISE" USING SERVICE-NAME
                        PROGRAM-REC
                        TPSTATUS-REC.

IF NOT TPOK
    error processing
*****
* Unadvertise TLRINIT service  (yourself)
*****
MOVE "TLRINIT" TO SERVICE-NAME.
CALL "TPUNADVERTISE" USING SERVICE-NAME
                        TPSTATUS-REC.

IF NOT TPOK
    error processing

```

Building Servers

To build an executable ATMI server, compile your application service subroutines with the Oracle Tuxedo system server adaptor and all other referenced files using the `buildserver(1)` command with the `-C` option.

Note: The Oracle Tuxedo server adaptor accepts messages, dispatches work, and manages transactions (if transactions are enabled).

Use the following syntax for the `buildserver` command:

```
buildserver -C -o filename -f filenames -l filenames -s -v
```

[Table 5-5](#) describes the `buildserver` command-line options:

Table 5-5 buildserver Command-line Options

This Option . . .	Allows You to Specify the . . .
<code>-o filename</code>	Name of the executable output file. The default is SERVER.
<code>-f filenames</code>	List of files that are link edited before the Oracle Tuxedo system libraries. You can specify the <code>-f</code> option more than once, and multiple filenames for each occurrence of <code>-f</code> . If you specify a COBOL program file (<i>file.cbl</i>), it is compiled before it is linked. You can specify other object files (<i>file.o</i>) separately, or in groups in an archive file (<i>file.a</i>).
<code>-l filenames</code>	List of files that are link edited after the Oracle Tuxedo system libraries. You can specify the <code>-l</code> option more than once, and multiple filenames for each occurrence of <code>-l</code> . If you specify a COBOL program file (<i>file.cbl</i>), it is compiled before it is linked. You can specify other object files (<i>file.o</i>) separately, or in groups in an archive file (<i>file.a</i>).
<code>-r filenames</code>	List of resource manager access libraries that are link edited with the executable server. The application administrator is responsible for predefining all valid resource manager information in the <code>\$TUXDIR/updataobj/RM</code> file using the <code>buildtms(1)</code> command. You can specify only one resource manager. Refer to <i>Setting Up an Oracle Tuxedo Application</i> for more information.
<code>-s [service:]routine</code>	<p>Name of service or services offered by the server and the name of the routine that performs each service. You can specify the <code>-s</code> option more than once, and multiple services for each occurrence of <code>-s</code>. The server uses the specified service names to advertise its services to clients.</p> <p>Typically, you should assign the same name to both the service and the routine that performs that service. Alternatively, you can specify any names. To assign names, use the following syntax: <i>service:routine</i>.</p>

Notes: The Oracle Tuxedo libraries are linked in automatically. You do not need to specify the Oracle Tuxedo library names on the command line.

Link editing must be done by running the `buildclient` command.

The order in which you specify the library files to be link edited is significant: it depends on the order in which routines are called and which libraries contain references to those functions.

By default, the `buildserver` command invokes the UNIX `cobcc` command, which uses the MicroFocus Net Express compiler. To use Fujitsu's NetCOBOL `ALTCC` must be set, even on a Windows system. You must set `ALTCC=cobcc85` for NetCOBOL. You can specify an alternative compile command and set your own flags for the compile and link-edit phases, however, by setting the `ALTCC` and `ALTCFLAGS` environment variables, respectively. For more information, refer to [“Setting Environment Variables”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

Note: On a Windows system, the `ALTCC` and `ALTCFLAGS` environment variables are not applicable and setting them will produce unexpected results. You must compile your application first using a COBOL compiler and then pass the resulting object file to the `buildserver` command.

The following command processes the `acct.o` application file and creates a server called `ACCT` that contains two services: `NEW_ACCT`, which calls the `OPEN_ACCT` routine, and `CLOSE_ACCT`, which calls a routine of the same name.

```
buildserver -C -o ACCT -f acct.o -s NEW_ACCT:OPEN_ACCT -s CLOSE_ACCT
```

Writing Request/Response Clients and Servers

This topic includes the following sections:

- [Overview of Request/Response Communication](#)
- [Sending Synchronous Messages](#)
- [Sending Asynchronous Messages](#)
- [Setting and Getting Message Priorities](#)

Overview of Request/Response Communication

In request/response communication mode, one software module sends a request to a second software module and waits for a response. Because the first software module performs the role of the client, and the second, the role of the server, this mode is also referred to as client/server interaction. Many online banking tasks are programmed in request/response mode. For example, a request for an account balance is executed as follows:

1. A customer (the client) sends a request for an account balance to the Account Record Storage System (the server).
2. The Account Record Storage System (the server) sends a reply to the customer (the client), specifying the dollar amount in the designated account.

Figure 6-1 Example of Request/Response Communication in Online Banking

Once a client process has joined an application, it can then send the request message to a service subroutine for processing and receive a reply message.

Sending Synchronous Messages

The `TPCALL(3cbl)` call sends a request to a service subroutine and synchronously waits for a reply. Use the following signature to call the `TPCALL` routine:

```

01 TPSVCDEF-REC.
   COPY TPSVCDEF.
01 ITPTYPE-REC.
   COPY TPTYPE.
01 IDATA-REC.
   COPY User Data.
01 OTPTYPE-REC.
   COPY TPTYPE.
01 ODATA-REC.
   COPY User Data.
01 TPSTATUS-REC.
   COPY TPSTATUS.
CALL "TPCALL" USING TPSVCDEF-REC
                    ITPTYPE-REC
                    IDATA-REC
                    OTPTYPE-REC
                    ODATA-REC
                    TPSTATUS-REC.
  
```

For more information on the TPSVCDEF data structure, refer to [Programming Oracle Tuxedo ATMI Applications Using C](#). The IDATA-REC and ITPTYPE-REC structures define the request record. The ODATA-REC and OTPTYPE-REC structures define the reply record. The ITPTYPE-REC and OTPTYPE-REC data structures are similar to the TPTYPE-REC data structure.

TPCALL waits for the expected reply.

Note: Calling the TPCALL routine is logically the same as calling the TPACALL routine, immediately followed by TPGETRPLY, as described in [“Sending Asynchronous Messages”](#) on page 6-10.

The request carries the priority set by the system for the specified service (SERVICE-NAME) unless a different priority has been explicitly set by a call to the TPSPRIO routine (described in [“Setting and Getting Message Priorities”](#) on page 6-15).

TPCALL returns an integer. On failure, the value of TP-STATUS is set to a value that reflects the type of error that occurred. For information on valid error codes, refer to [TPCALL\(3cb1\)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference*.

Note: Communication calls may fail for a variety of reasons, many of which can be corrected at the application level. Possible causes of failure include: application defined errors (TPESVCFAIL), errors in processing return arguments (TPESVCERR), typed record errors (TPEITYPE, TPEOTYPE), timeout errors (TPETIME), and protocol errors (TPEPROTO), among others. For a detailed discussion of errors, refer to [“Managing Errors”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*. For a complete list of possible errors, refer to [TPCALL\(3cb1\)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference*.

The Oracle Tuxedo system automatically adjusts a record used for receiving a message if the received message is too large for the allocated record. You should test for whether or not the reply records have been resized.

To access the new size of the record, use the address returned in *LEN IN OTPTYPE-REC. To determine whether a reply record has changed in size, compare the size of the reply record before the call to TPCALL with the value of LEN IN OTPTYPE-REC after its return. If LEN IN OTPTYPE-REC is larger than the original size, the record has grown. If not, the record size has not changed.

Example: Using the Same Record for Request and Reply Messages

The following example shows how the client program makes a synchronous call using the same record for both the request and reply messages. In this case, using the same record is appropriate

because the AUDV-REC message record has been set up to accommodate both request and reply information. The following actions are taken in this code:

1. The service queries the B_ID field, but does not overwrite it.
2. The application initializes the BALANCE field to zero in preparation for the values to be returned by the service.
3. The SERVICE-NAME represents the service name requested. In this example, these variables represent account and teller, respectively.

Listing 6-1 Using the Same Record for Request and Reply Messages

```

        COPY AUDV.
```

```

*
*****

    PROCEDURE DIVISION.
    START-FIG.
    MOVE LENGTH OF LOGMSG TO LOGMSG-LEN.
*****
*   Prepare the audv record
*****

    MOVE "BRANCH" TO B-ID IN AUDV-REC.
    MOVE 0 TO BALANCE IN AUDV-REC.
    MOVE LENGTH OF AUDV-REC TO LEN.
    MOVE "VIEW" TO REC-TYPE.
    MOVE "audv" TO SUB-TYPE.
    MOVE "SOMESERVICE" TO SERVICE-NAME.
    SET TPBLOCK TO TRUE.
    SET TPNOTRAN TO TRUE.
    SET TPNOTIME TO TRUE.
    SET TPSIGRSTRT TO TRUE.
    SET TPNOCHANGE TO TRUE.
    CALL "TPCALL" USING TPSVCDEF-REC
                        TPTYPE-REC
                        AUDV-REC
                        TPTYPE-REC
                        AUDV-REC
                        TPSTATUS-REC.

    IF NOT TPOK
        MOVE "Service Failed" TO LOGMSG-TEXT
        PERFORM DO-USERLOG
        PERFORM EXIT-PROGRAM.

    DISPLAY BRANCH and BALANCE
    . . .

```

If the reply is larger than ODATA-REC, then ODATA-REC contains as much of the message as fits in the record. The remainder is discarded and TPCALL sets TP-STATUS IN TPSTATUS-REC to TPTRUNCATE.

Example: Sending a Synchronous Message with TPSIGRSTRT Set

The following example is based on the `TRANSFER` service, which is part of the `XFER` server process of `bankapp`. (`bankapp` is a sample ATMI application delivered with the Oracle Tuxedo system.) The example is based on a service that assumes the role of a client when it calls the `WITHDRAWAL` and `DEPOSIT` services. The application sets the communication flag to `TPSIGRSTRT` in these service calls to give the transaction a better chance of committing. The `TPSIGRSTRT` flag specifies the action to take if there is a signal interrupt. For more information on communication flags, refer to [TPCALL\(3cbl\)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference*.

Example: Sending a Synchronous Message with TPNOTRAN Set

The following example illustrates a communication call that suppresses transaction mode. The call is made to a service that is not affiliated with a resource manager; it would be an error to allow the service to participate in the transaction. The application prints an accounts receivable report, ACCRV, generated from information obtained from a database named ACCOUNTS.

The service routine REPORT interprets the specified parameters and sends the byte stream for the completed report as a reply. The client uses TPCALL to send the byte stream to a service called PRINTER, which, in turn, sends the byte stream to a printer that is conveniently close to the client. The reply is printed. Finally, the PRINTER service notifies the client that the hard copy is ready to be picked up.

Note: The example “[Sending an Asynchronous Message with TPNOTRAN or TPNOREPLY](#)” on page 6-12 shows a similar example using an asynchronous message call.

                     TPSTATUS-REC.

IF NOT TPOK
    error processing
. . .
    terminate transaction
    leave application

```

Note: In the preceding example, the term *error routine* indicates that the following tasks are performed: an error message is printed, the transaction is aborted, the client leaves the application, and the program is exited.

This example also shows how the `TPNOCHANGE` communication setting is used to enforce strong record type checking by indicating that the reply message must be returned in the same type of record that was originally allocated. The strong type check flag, `TPNOCHANGE`, forces the reply to be returned in a record of type `STRING`.

A possible reason for this check is to guard against errors that may occur in the `REPORT` service subroutine, resulting in the use of a reply record of an incorrect type. Another reason is to prevent changes that are not made consistently across all areas of dependency. For example, another programmer may have changed the `REPORT` service to standardize all replies in another `STRING` format without modifying the client process to reflect the change.

Sending Asynchronous Messages

This section explains how to:

- Send an asynchronous request using the `TPACALL` routine
- Get an asynchronous reply using the `TPGETRPLY` routine

The type of asynchronous processing discussed in this section is sometimes referred to as *fan-out parallelism* because it allows a client's requests to be distributed (or "fanned out") simultaneously to several services for processing.

The other type of asynchronous processing supported by the Oracle Tuxedo system is pipeline parallelism in which the `TPFORWAR` routine is used to pass (or forward) a process from one service to another. For a description of the `TPFORWAR` routine, refer to ["Writing Servers"](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

Sending an Asynchronous Request

The `TPACALL(3cbl)` routine sends a request to a service and immediately returns. Use the following signature to call the `TPACALL` routine:

```
01 TPSVCDEF-REC .
   COPY TPSVCDEF .
01 TPTYPE-REC .
   COPY TPTYPE .
01 DATA-REC .
   COPY User Data .
01 TPSTATUS-REC .
   COPY TPSTATUS .
CALL "TPACALL" USING TPSVCDEF-REC TPTYPE-REC DATA-REC TPSTATUS-REC .
```

For more information on the `TPSVCDEF` and `TPTYPE-REC` data structures, refer to ["Defining a Service"](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

The `TPACALL` routine sends a request message to the service named in the `SERVICE-NAME` and immediately returns from the call. Upon successful completion of the call, the `TPACALL` routine returns an integer that serves as a communication handle used to access the correct reply for the relevant request. While `TPACALL` is in transaction mode (as described in ["Writing Global Transactions"](#) in *Programming Oracle Tuxedo ATMI Applications Using C*) there may not be any outstanding replies when the transaction commits; that is, within a given transaction, for each request for which a reply is expected, a corresponding reply must eventually be received.

If the value `TPNOREPLY` is set, the parameter signals to `TPACALL` that a reply is not expected. When set, on success `TPACALL` returns a value of 0 as the reply descriptor. If subsequently passed to the `TPGETRPLY` routine, this value becomes invalid, this value becomes invalid. Guidelines for using this setting correctly when a process is in transaction mode are discussed in ["Writing Global Transactions"](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

On error, TPACALL sets TP-STATUS to a value that reflects the nature of the error. TPACALL returns many of the same error codes as TPCALL. The differences between the error codes for these functions are based on the fact that one call is synchronous and the other, asynchronous. These errors are discussed at length in [“Managing Errors”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

The following example shows how TPACALL uses the TPNOTRAN and TPNOREPLY settings. This code is similar to the code in [“Example: Sending a Synchronous Message with TPNOTRAN Set”](#) on page 6-8. In this case, however, a reply is not expected from the PRINTER service. By setting both TPNOTRAN and TPNOREPLY, the client is indicating that no reply is expected and the PRINTER service will not participate in the current transaction. This situation is discussed more fully in [“Managing Errors”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

Getting an Asynchronous Reply

A reply to a service call can be received asynchronously by calling the [TPGETRPLY\(3cbl\)](#) routine. The TPGETRPLY routine dequeues a reply to a request previously sent by TPACALL.

Use the following signature to call the TPGETRPLY routine:

```

01 TPSVCDEF-REC.
   COPY TPSVCDEF.
01 TPTYPE-REC.
   COPY TPTYPE.
01 DATA-REC.
   COPY User Data.
01 TPSTATUS-REC.
   COPY TPSTATUS.
CALL "TPGETRPLY" USING TPSVCDEF-REC TPTYPE-REC DATA-REC TPSTATUS-REC.

```

For more information on the TPSVCDEF and TPTYPE-REC data structures, refer to “[Defining a Service](#)” in *Programming Oracle Tuxedo ATMI Applications Using C*.

By default, the function waits for the arrival of the reply that corresponds to the value referenced by the communication handle. During this waiting interval, a blocking timeout may occur. A time-out occurs when TPGETRPLY fails and TP-STATUS is set to TPETIME (unless TPNOTIME is set).

Setting and Getting Message Priorities

Two ATMI calls allow you to determine and set the priority of a message request: `TPSPRIO(3cbl)` and `TPGPRIOR(3cbl)`. The priority affects how soon the request is dequeued by the server; servers dequeue requests with the highest priorities first.

This section describes:

- [Setting a Message Priority](#)
- [Getting a Message Priority](#)

Setting a Message Priority

The `TPSPRIO(3cbl)` routine enables you to set the priority of a message request.

The `TPSPRIO` routine affects the priority level of only one request: the next request to be sent by `TPCALL` or `TPACALL`, or to be forwarded by a service subroutine.

Use the following signature to call the `TPSPRIO` routine:

```
01  TPPRIDEF-REC.
    COPY  TPPRIDEF.
01  TPSTATUS-REC.
    COPY  TPSTATUS.
CALL "TPSPRIO" USING TPPRIDEF-REC TPSTATUS-REC.
```

Use the following signature for the `TPPRIDEF-REC` data structure.

```
05  PRIORITY      PIC  S9(9)  COMP-5.
05  PRIO-FLAG     PIC  S9(9)  COMP-5.
    88  TPABSOLUTE      VALUE  0.
    88  TPRELATIVE     VALUE  1.
```

[Table 6-1](#) describes the arguments to the `TPSPRIO` routine.

Table 6-1 TPSPRIO Routine Fields

Field	Description
PRIORITY	Integer indicating a new priority value. The effect of this argument is controlled by PRIO-FLAG. If PRIO-FLAG is set to 0, PRIORITY specifies a relative value and the sign accompanying the value indicates whether the current priority is incremented or decremented. Otherwise, the value specified indicates an absolute value and PRIORITY must be set to a value between 0 and 100. If you do not specify a value within this range, the system sets the value to 50.
PRIO-FLAG	Indicates whether the value of PRIORITY is treated as a relative value (0, the default) or an absolute value (TPABSOLUTE).

The following sample code is an excerpt from the TRANSFER service. In this example, the TRANSFER service acts as a client by sending a synchronous request, via TPCALL, to the WITHDRAWAL service. TRANSFER also invokes TPSPRIO to increase the priority of its request message to WITHDRAWAL, and to prevent the request from being queued for the WITHDRAWAL service (and later the DEPOSIT service) after waiting on the TRANSFER queue.

Listing 6-5 Setting the Priority of a Request Message

                           DATA-REC
                           TPSTATUS-REC.

      IF NOT TPOK
         error processing
      . . .
      leave application

```

Getting a Message Priority

The [TPGPRIO\(3cbl\)](#) routine enables you to get the priority of a message request.

Use the following signature to call the TPGPRIO routine:

```
01 TPRIDEF-REC.  
   COPY TPRIDEF.  
01 TPSTATUS-REC.  
   COPY TPSTATUS.  
CALL "TPGPRIO" USING TPRIDEF-REC TPSTATUS-REC.
```

A requester can call the TPGPRIO routine after invoking the TPCALL or TPACALL routine to retrieve the priority of the request message. If a requester calls the function but no request is sent, the routine fails, setting TP-STATUS to TPENOENT. Upon success, TPGPRIO sets TP-STATUS to TPOK and returns an integer value in the range of 1 to 100 (where the highest priority value is 100).

If a priority has not been explicitly set using the TSPRIO routine, the system sets the message priority to that of the service routine that handles the request. Within an application, the priority of the request-handling service is assigned a default value of 50 unless a system administrator overrides this value.

The following example shows how to determine the priority of a message that was sent in an asynchronous call.

Listing 6-6 Determining the Priority of the Sent Request

Writing Conversational Clients and Servers

This topic includes the following sections:

- [Overview of Conversational Communication](#)
- [Joining an Application](#)
- [Establishing a Connection](#)
- [Sending and Receiving Messages](#)
- [Ending a Conversation](#)
- [Building Conversational Clients and Servers](#)
- [Understanding Conversational Communication Events](#)

Overview of Conversational Communication

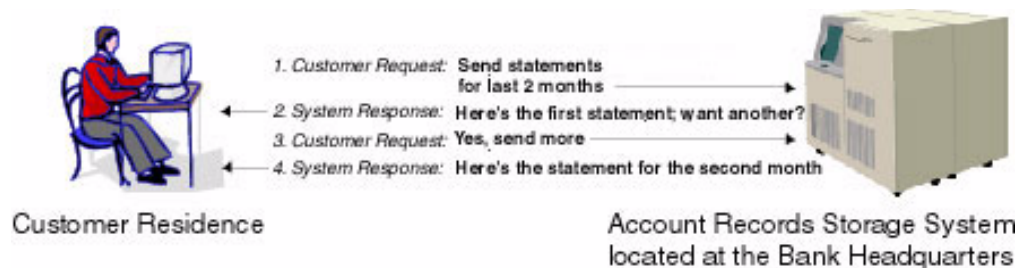

Conversational communication is the Oracle Tuxedo system implementation of a human-like paradigm for exchanging messages between ATMI clients and servers. In this form of communication, a virtual connection is maintained between the client (initiator) and server (subordinate) and each side maintains information about the state of the conversation. The connection remains active until an event occurs to terminate it.

During conversational communication, a *half-duplex* connection is established between the client and server. A half-duplex connection allows messages to be sent in only one direction at any given time. Control of the connection can be passed back and forth between the initiator and the

subordinate. The process that has control can send messages; the process that does not have control can only receive messages.

To understand how conversational communication works in an Oracle Tuxedo ATMI application, consider the following example from an online banking application. In this example, a bank customer requests checking account statements for the past two months.

Figure 7-1 Example of Conversational Communication in an Online Banking Application

1. The customer requests the checking account statements for the past two months.
2. The Account Records Storage System responds by sending the first month's checking account statement followed by a `More` prompt for accessing the remaining month's statement.
3. The customer requests the second month's account statement by selecting the `More` prompt.

Note: The Account Records Storage System must maintain state information so it knows which account statement to return when the customer selects the `More` prompt.

4. The Account Records Storage System sends the remaining month's account statement.

As with request/response communication, the Oracle Tuxedo system passes data using typed records. The record types must be recognized by the application. For more information on record types, refer to [“Overview of Typed Records” on page 3-1](#).

Conversational clients and servers have the following characteristics:

- The logical connection between them remains active until terminated.
- Any number of messages can be transmitted across a connection between them.
- Both clients and servers use the `TPSEND` and `TPRCV` routines to send and receive data in conversations.

Conversational communication differs from request/response communication in the following ways:

- A conversational client initiates a request for service using `TPCONNECT` rather than `TPCALL` or `TPACALL`.
- A conversational client sends a service request to a conversational server.
- The configuration file reserves part of the conversational server for addressing conversational services.
- Conversational servers are prohibited from making calls using `TPFORWAR`.

Joining an Application

A conversational client must join an application via a call to `TPINITIALIZE` before attempting to establish a connection to a service. For more information, refer to [“Writing Clients”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

Establishing a Connection

The `TPCONNECT(3cbl)` routine sets up a conversation:

Use the following signature to call the `TPCONNECT` routine.

```
01 TPSVCDEF-REC.
   COPY TPSVCDEF.

01 TPTYPE-REC.
   COPY TPTYPE.

01 DATA-REC.
   COPY User Data.

01 TPSTATUS-REC.
   COPY TPSTATUS.

CALL "TPCONNECT" USING TPSVCDEF-REC TPTYPE-REC DATA-REC TPSTATUS-REC.
```

Refer to [“Defining a Service”](#) for more information on the `TPSVCDEF-REC` record, and to [“Defining Typed Records”](#) on page 3-6 for more information on the `TPTYPE-REC` record.

At the same time the connection is being established, data can be sent through the `DATA-REC` with the length of the data specified by `LEN` in `TPTYPE-REC`. The `REC-TYPE` and `SUB-TYPE` of the data in `DATA-REC` must be types recognized by the service being called. If no data is being sent, the value of `REC-TYPE` is `SPACES`, and `DATA-REC` and `LEN` are ignored.

The Oracle Tuxedo system returns a communication handle, `COMM-HANDLE` in `TPSVCDEF-REC`, when a connection is established with `TPCONNECT` or `TPSVCSTART`. `COMM-HANDLE` is used to

identify subsequent message transmissions with a particular conversation. A client or conversational service can participate in more than one conversation simultaneously. The maximum number of simultaneous conversations is 64.

In the event of a failure, TPCONNECT sets TP-STATUS to the appropriate error condition. For a list of possible error codes, refer to [TPCONNECT\(3cbl \)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference*.

The following example shows how to use the TPCONNECT routine.

Listing 7-1 Establishing a Conversational Connection

```
      . . .
* Prepare the record to send
  MOVE "HELLO" TO DATA-REC.
  MOVE 5 TO LEN.
  MOVE "STRING" TO REC-TYPE.
*
  SET TPBLOCK TO TRUE.
  SET TPNOTRAN TO TRUE.
  SET TPNOTIME TO TRUE.
  SET TPSIGRSTRT TO TRUE.
  SET TPSENDONLY TO TRUE.
*
  CALL "TPCONNECT" USING TPSVCDEF-REC
                        TPTYPE-REC
                        DATA-REC
                        TPSTATUS-REC.

  IF NOT TPOK
      error processing ...
  ELSE
      COMM-HANDLE is valid.
```

Sending and Receiving Messages

Once the Oracle Tuxedo system establishes a conversational connection, communication between the initiator and subordinate is accomplished using send and receive calls. The process

with control of the connection can send messages using the `TPSEND(3cbl)` routine; the process without control can receive messages using the `TPRECV(3cbl)` routine.

Note: Initially, the originator (that is, the client) decides which process has control using the `TPSENDONLY` or `TPRECVONLY` flag value of the `TPCONNECT` call. `TPSENDONLY` specifies that control is being retained by the originator; `TPRECVONLY`, that control is being passed to the called service.

Sending Messages

To send a message, use the `TPSEND(3cbl)` routine with the following signature:

```
01 TPSVCDEF-REC.
   COPY TPSVCDEF.

01 TPTYPE-REC.
   COPY TPTYPE.

01 DATA-REC.
   COPY User Data.

01 TPSTATUS-REC.
   COPY TPSTATUS.

CALL "TPSEND" USING TPSVCDEF-REC TPTYPE-REC USER-DATA-REC TPSTATUS-REC.
```

Refer to [“Defining a Service”](#) in *Programming Oracle Tuxedo ATMI Applications Using C* for more information on the `TPSVCDEF-REC` record, and refer to [“Defining Typed Records” on page 3-6](#) for more information on the `TPTYPE-REC` record.

In the event of a failure, the `TPSEND` routine sets `TP-STATUS` to the appropriate error condition. For a list of possible error codes, refer to `TPSEND(3cbl)` in the *Oracle Tuxedo ATMI COBOL Function Reference*.

You are not required to pass control each time you issue the `TPSEND` routine. In some applications, the process authorized to issue `TPSEND` calls can execute as many calls as required by the current task before turning over control to the other process. In other applications, however, the logic of the program may require the same process to maintain control of the connection throughout the life of the conversation.

The following example shows how to invoke the `TPSEND` routine.

Listing 7-2 Sending Data in Conversational Mode

```
. . .  
SET TPNOBLOCK TO TRUE.  
SET TPNOTIME TO TRUE.  
SET TPSIGRSTRT TO TRUE.  
SET TPRECONLY TO TRUE.  
*  
CALL "TPSEND" USING TPSVCDEF-REC  
                    TPTYPE-REC  
                    DATA-REC  
                    TPSTATUS-REC.  
  
IF NOT TPOK  
    error processing . . .
```

Receiving Messages

To receive data sent over an open connection, use the [TPRECV\(3cbl\)](#) routine with the following signature:

```
01 TPSVCDEF-REC.  
    COPY TPSVCDEF.  
  
01 TPTYPE-REC.  
    COPY TPTYPE.  
  
01 DATA-REC.  
    COPY User Data.  
  
01 TPSTATUS-REC.  
    COPY TPSTATUS.  
  
CALL "TPRECV" USING TPSVCDEF-REC TPTYPE-REC DATA-REC TPSTATUS-REC.
```

Refer to [“Defining a Service”](#) for more information on the TPSVCDEF-REC record. Refer to [“Defining Typed Records” on page 3-6](#) for more information on the TPTYPE-REC record.

The following example shows how to use the TPRECV routine.

Listing 7-3 Receiving Data in Conversation

```

. . .
SET TPNOCHANGE TO TRUE.
SET TPBLOCK TO TRUE.
SET TPNOTIME TO TRUE.
SET TPSIGRSTRT TO TRUE.
*
MOVE LENGTH OF DATA-REC TO LEN.
*
CALL "TPRECV" USING TPSVCDEF-REC
                    TPTYPE-REC
                    DATA-REC
                    TPSTATUS-REC.

IF NOT TPOK
    error processing . . .

```

Ending a Conversation

A connection can be taken down gracefully and a conversation ended normally through:

- A successful call to `TPRETURN` in a simple conversation.
- A series of successful calls to `TPRETURN` in a complex conversation based on a hierarchy of connections.
- Global transactions, as described in [“Writing Global Transactions”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

Note: The `TPRETURN` routine is described in detail in [“Writing Request/Response Clients and Servers”](#) in *Programming Oracle Tuxedo ATMI Applications Using C*.

The following sections describe two scenarios for gracefully terminating conversations that do not include global transactions in which the `TPRETURN` function is used.

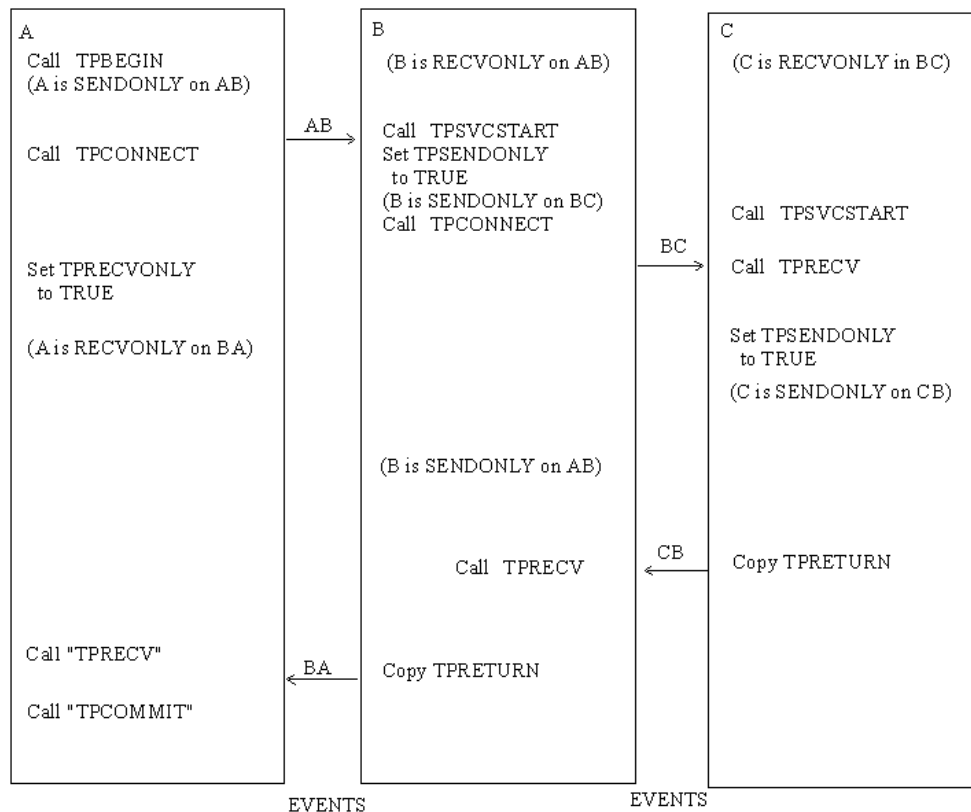

The first example shows how to terminate a simple conversation between two components. The second example illustrates a more complex scenario, with a hierarchical set of conversations.

If you end a conversation with connections still open, the system returns an error. In this case, either `TPCOMMIT` or `TPRETURN` fails in a disorderly manner.

Example: Ending a Simple Conversation

Figure 7-2 shows a simple conversation between A and B that terminates gracefully.

Figure 7-2 Simple Conversation Terminating Gracefully

The program flow is as follows:

1. A sets up the connection by calling `TPCONNECT` with `TPSENDONLY` set, indicating that process B is on the receiving end of the conversation.
2. A turns control of the connection over to B by calling `TPSEND` with `TPRECVONLY` set, resulting in the generation of a `TPEV_SENDONLY` event.
3. The next call by B to `TPRECV` sets `TP-STATUS` to `TPEEVEVENT`, and returns `TPEV_SENDONLY` in `TPEVENT`, indicating that control has passed to B.

4. B calls `TPRETURN` with `TPRETURN-VAL` IN `TPSVCRET` set to `TPSUCCESS`. This call generates a `TPEV_SVCSUCC` event for A and gracefully brings down the connection.
5. A calls `TPRECV`, learns of the event, and recognizes that the conversation has been terminated. Data can be received on this call to `TPRECV` even if the event is set to `TPEV_SVCFAIL`.

Note: In this example, A can be either a client or a server, but B must be a server.

Example: Ending a Hierarchical Conversation

Figure 7-3 shows a hierarchical conversation that terminates gracefully.

Figure 7-3 Connection Hierarchy

In the preceding example, service B is a member of a conversation that has initiated a connection to a second service called C. In other words, there are two active connections: A-to-B and B-to-C. If B is in control of both connections, a call to `TPRETURN` has the following effect: the call fails, a `TPEV_SVCERR` event is posted on all open connections, and the connections are closed in a disorderly manner.

In order to terminate both connections normally, an application must execute the following sequence:

1. B calls `TPSEND` with the `TPRECVONLY` flag set on the connection to C, transferring control of the B-to-C connection to C.
2. C calls `TPRETURN` with `TPRETURN-VAL` IN `TPSVCRET` set to `TPSUCCESS`, `TPFAIL`, or `TPEXIT`, as appropriate.
3. B can then call `TPRETURN`, posting an event (either `TPEV_SVCSUCC` or `TPEV_SVCFAIL`) for A.

Note: It is legal for a conversational service to make request/response calls if it needs to do so to communicate with another service. Therefore, in the preceding example, the calls from B to C may be executed using `TPCALL` or `TPACALL` instead of `TPCONNECT`. Conversational services are not permitted to make calls to `TPFORWAR`.

Executing a Disorderly Disconnect

The only way in which a disorderly disconnect can be executed is through a call to the `TPDISCON(3cbl)` routine (which is equivalent to “pulling the plug” on a connection). This routine can be called only by the initiator of a conversation (that is, the client).

Note: This is not the preferred method for bringing down a conversation. To bring down an application gracefully, the subordinate (the server) should call the `TPRETURN` routine.

Use the following signature to call the `TPDISCON` routine:

```
01 TPSVCDEF-REC.  
   COPY TPSVCDEF.  
  
01 TPSTATUS-REC.  
   COPY TPSTATUS.  
  
CALL "TPDISCON" USING TPSVCDEF-REC TPSTATUS-REC.
```

The `COMM-HANDLE` argument specifies the communication handle returned by the `TPCONNECT` routine when the connection is established.

The `TPDISCON` routine generates a `TPEV_DISCONIMM` event for the service at the other end of the connection, rendering the `COMM-HANDLE` invalid. If a transaction is in progress, the system aborts it and data may be lost.

If `TPDISCON` is called from a service that was not the originator of the connection identified by `COMM-HANDLE`, the routine fails with an error code of `TPEBADDESC`.

For a list and descriptions of all event and error codes, refer to [TPDISCON\(3cbl\)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference*.

Building Conversational Clients and Servers

Use the following commands to build conversational clients and servers:

- `buildclient()` as described in “Building Clients” in *Programming Oracle Tuxedo ATMI Applications Using C*
- `buildserver()` as described in “Building Servers” in *Programming Oracle Tuxedo ATMI Applications Using C*

For conversational and request/response services, you cannot:

- Build both in the same server
- Assign the same name to both

Understanding Conversational Communication Events

The Oracle Tuxedo system recognizes five events in conversational communication. All five events can be posted for `TPRECV`; three can be posted for `TPSEND`.

[Table 7-1](#) lists the events, the routines for which they are returned, and a detailed description of each.

Table 7-1 Conversational Communication Events

Event	Received By	Description
<code>TPEV_SENDOONLY</code>	<code>TPRECV</code>	Control of the connection has been passed; this process can now call <code>TPSEND</code> .
<code>TPEV_DISCONIMM</code>	<code>TPSEND</code> , <code>TPRECV</code> , <code>TPRETURN</code>	The connection has been torn down and no further communication is possible. The <code>TPDISCON</code> routine posts this event in the originator of the connection, and sends it to all open connections when <code>TPRETURN</code> is called, as long as connections to subordinate services remain open. Connections are closed in a disorderly fashion. If a transaction exists, it is aborted.

Table 7-1 Conversational Communication Events

Event	Received By	Description
TPEV_SVCERR	TPSEND	Received by the originator of the connection, usually indicating that the subordinate program issued a TPRETURN without having control of the connection.
	TPRECV	Received by the originator of the connection, indicating that the subordinate program issued a TPRETURN with TPSUCCESS or TPFAIL and a valid data record, but an error occurred that prevented the call from completing.
TPEV_SVCFAIL	TPSEND	Received by the originator of the connection, indicating that the subordinate program issued a TPRETURN without having control of the connection, and TPRETURN was called with TPFAIL or TPEXIT and no data.
	TPRECV	Received by the originator of the connection, indicating that the subordinate service finished unsuccessfully (TPRETURN was called with TPFAIL or TPEXIT).
TPEV_SVCSUCC	TPRECV	Received by the originator of the connection, indicating that the subordinate service finished successfully; that is, it called TPRETURN with TPSUCCESS.

Writing Event-based Clients and Servers

This topic includes the following sections:

- [Overview of Events](#)
- [Defining the Unsolicited Message Handler](#)
- [Sending Unsolicited Messages](#)
- [Checking for Unsolicited Messages](#)
- [Getting Unsolicited Messages](#)
- [Subscribing to Events](#)
- [Unsubscribing from Events](#)
- [Posting Events](#)

Overview of Events

Event-based communication provides a method for an Oracle Tuxedo system process to be notified when a specific situation (event) occurs.

The Oracle Tuxedo system supports two types of event-based communication:

- Unsolicited events
- Brokered events

Unsolicited Events

Unsolicited events are messages used to communicate with client programs that are not waiting for and/or expecting a message.

Brokered Events

Brokered events enable a client and a server to communicate transparently with one another via an “anonymous” broker that receives and distributes messages. Such brokering is another client/server communication paradigm that is fundamental to the Oracle Tuxedo system.

The EventBroker is an Oracle Tuxedo subsystem that receives and filters event posting messages, and distributes them to subscribers. A *poster* is an Oracle Tuxedo system process that detects when a specific event has occurred and reports (posts) it to the EventBroker. A *subscriber* is an Oracle Tuxedo system process with a standing request to be notified whenever a specific event has been posted.

The Oracle Tuxedo system does not impose a fixed ratio of service requesters to service providers; an arbitrary number of posters can post a message for an arbitrary number of subscribers. The posters simply post events, without knowing which processes receive the information or how the information is handled. Subscribers are notified of specified events, without knowing who posted the information. In this way, the EventBroker provides complete location transparency.

Typically, EventBroker applications are designed to handle exception events. An application designer must decide which events in the application constitute exception events and need to be monitored. In a banking application, for example, it might be useful to post an event whenever an unusually large amount of money is withdrawn, but it would not be particularly useful to post an event for every withdrawal transaction. In addition, not all users would need to subscribe to that event; perhaps only the branch manager would need to be notified.

Notification Actions

The EventBroker may be configured such that whenever an event is posted, the EventBroker invokes one or more notification actions for clients and/or servers that have subscribed. [Table 8-1](#) lists the types of notification actions that the EventBroker can take.

Table 8-1 EventBroker Notification Actions

Notification Action	Description
Unsolicited notification message	Clients may receive event notification messages in their unsolicited message handling routine, just as if they were sent by the <code>TPNOTIFY</code> routine.
Service call	Servers may receive event notification messages as input to service routines, just as if they were sent by <code>TPACALL</code> .
Reliable queue	Event notification messages may be stored in an Oracle Tuxedo system reliable queue, using <code>TPDEQUEUE (3cb1)</code> . Event notification records are stored until requests for contents are issued. An Oracle Tuxedo system client or server process may call <code>TPDEQUEUE (3cb1)</code> to retrieve these notification records, or alternately <code>TMQFORWARD (5)</code> may be configured to automatically dispatch an Oracle Tuxedo system service routine that retrieves a notification record. For more information on /Q, see <i>Using the ATMI /Q Component</i> .

In addition, the application administrator may create an `EVENT_MIB (5)` entry (by using the Oracle Tuxedo administrative API) that performs the following notification actions:

- Invokes a system command
- Writes a message to the system's log file on disk

Note: Only the Oracle Tuxedo application administrator is allowed to create an `EVENT_MIB (5)` entry.

For information on the `EVENT_MIB (5)`, refer to the *File Formats, Data Descriptions, MIBs, and System Processes Reference*.

EventBroker Servers

`TMUSREVT` is the Oracle Tuxedo system-supplied server that acts as an EventBroker for *user events*. `TMUSREVT` processes event report message records, and then filters and distributes them. The Oracle Tuxedo application administrator must boot one or more of these servers to activate event brokering.

`TMSYSEVT` is the Oracle Tuxedo system-supplied server that acts as an EventBroker for *system-defined events*. `TMSYSEVT` and `TMUSREVT` are similar, but separate servers are provided to

allow the application administrator the ability to have different replication strategies for processing notifications of these two types of events. Refer to *Setting Up an Oracle Tuxedo Application* for additional information.

System-defined Events

The Oracle Tuxedo system itself detects and posts certain predefined events related to system warnings and failures. These tasks are performed by the EventBroker. For example, system-defined events include configuration changes, state changes, connection failures, and machine partitioning. For a complete list of system-defined events detected by the EventBroker, see [EVENTS \(5\)](#) in the *File Formats, Data Descriptions, MIBs, and System Processes Reference*.

System-defined events are defined in advance by the Oracle Tuxedo system code and do not require posting. The name of a system-defined event, unlike that of an application-defined event, always begins with a dot (“.”). Names of application-defined events may not begin with a leading dot.

Clients and servers can subscribe to system-defined events. These events, however, should be used mainly by application administrators, not by every client in the application.

When incorporating the EventBroker into your application, remember that it is not intended to provide a mechanism for high-volume distribution to many subscribers. Do not attempt to post an event for every activity that occurs, and do not expect all clients and servers to subscribe. If you overload the EventBroker, system performance may be adversely affected and notifications may be dropped. To minimize the possibility of overload, the application administrator should carefully tune the operating system IPC resources, as explained in *Installing the Oracle Tuxedo System*.

Programming Interface for the EventBroker

EventBroker programming interfaces are available for all Oracle Tuxedo system server and client processes, including Workstation, in both C and COBOL.

The programmer’s job is to code the following sequence:

1. A client or server *posts* a record to an application-defined event name.
2. The posted record is transmitted to any number of processes that have *subscribed* to the event.

Subscribers may be notified in a variety of ways (as discussed in “Notification Actions”), and events may be filtered. Notification and filtering are configured through the programming interface, as well as through the Oracle Tuxedo system administrative API.

Defining the Unsolicited Message Handler

To define the unsolicited message handler, use the [TPSETUNSOL\(3cbl\)](#) routine with the following signature:

```
01 CURR-ROUTINE    PIC S9(9) COMP-5.
01 PREV-ROUTINE    PIC S9(9) COMP-5.
01 TPSTATUS-REC.
    COPY TPSTATUS.
CALL "TPSETUNSOL" USING CURR-ROUTINE PREV-ROUTINE TPSTATUS-REC.
```

TPSETUNSOL allows a client to identify the routine that should be invoked when an unsolicited message is received by the Oracle Tuxedo system libraries. Before the first call to TPSETUNSOL, any unsolicited messages received by the Oracle Tuxedo system libraries on behalf of the client are logged and ignored. The method used by the system for notification and detection is determined by the application default, which can be overridden on a per-client basis. For more information, refer to [TPINITIALIZE\(3cbl\)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference*.

The CURR-ROUTINE parameter identifies one of 16 predefined routines that provide unsolicited message handling: eight C routines, `tm_displatch1` through `_tm_dispatch8`, and eight COBOL routines, `TMDISPATCH9` through `TMDISPATCH16`. (Alternatively, if you set CURR-ROUTINE to a value of 0, any unsolicited messages received by the Oracle Tuxedo system libraries on behalf of the client are logged and ignored.) The C routines must conform to the parameter definition provided on [TPSETUNSOL\(3cbl\)](#). When a COBOL routine is used, TPGETUNSOL must be called to receive the data.

The following sample code shows how to set an unsolicited routine in a COBOL program.

Listing 8-1 Setting an Unsolicited Routine

```
*
* Call TPSETUNSOL - Set a COBOL unsolicited message handler
* Routine TMDISPATCH9 will be called
*
MOVE 9 to CURR-ROUTINE.
CALL "TPSETUNSOL" USING
    CURR-ROUTINE
    PREV-ROUTINE
```

```

                                TPSTATUS-REC.
IF NOT TPOK
    Routine TMDISPATCH9 will receive unsolicited messages
ELSE
    Process error condition

```

Sending Unsolicited Messages

The Oracle Tuxedo system allows unsolicited messages to be sent to client processes without disturbing the processing of request/response calls or conversational communications.

Unsolicited messages can be sent to client processes by name, using [TPBROADCAST\(3cbl\)](#), or by an identifier received with a previously processed message, using [TPNOTIFY\(3cbl\)](#). Messages sent via TPBROADCAST can originate either in a service or in another client. Messages sent via TPNOTIFY can originate only in a service.

Broadcasting Messages by Name

The [TPBROADCAST\(3cbl\)](#) routine allows a message to be sent to registered clients of the application. It can be called by a service or another client. Registered clients are those that have successfully made a call to TPINITIALIZE and have not yet made a call to TPTERM.

Use the following signature to call the TPBROADCAST routine:

```

01 TPBCTDEF-REC.
   COPY TPBCTDEF.
01 TPTYPE-REC.
   COPY TPTYPE.
01 DATA-REC.
   COPY User Data.
01 TPSTATUS-REC.
   COPY TPSTATUS.
CALL "TPBROADCAST" USING TPBCTDEF-REC TPTYPE-REC DATA-REC TPSTATUS-REC.

```

[Table 8-2](#) describes the members of the TPBCTDEF-REC data structure.

Table 8-2 TPBCTDEF-REC Data Structure Members

Member	Description
LMID	Pointer to the logical machine identifier for the client. A value of SPACES acts as a wildcard, so that a message can be directed to groups of clients.
USERNAME	Username of the client process, if one exists. A value of SPACES acts as a wildcard, so that a message can be directed to groups of clients.
CLTNAME	Client name of the client process, if one exists. A value of NULL acts as a wildcard, so that a message can be directed to groups of clients.
Settings (such as TPBLOCK-FLAG)	Settings for the TPBROADCAST command. Refer to TPBROADCAST(3cbl) in the <i>Oracle Tuxedo ATMI COBOL Function Reference</i> for information on available settings.

Refer to “[Defining a Service](#)” in *Programming Oracle Tuxedo ATMI Applications Using C* for a description of the TPTYPE-REC record.

The following example illustrates a call to TPBROADCAST for which all clients are targeted. The message to be sent is contained in a STRING record.

Listing 8-2 Using TPBROADCAST

```

. . .
*****
* Prepare the record to broadcasted
*****
      MOVE "HELLO, WORLD" TO DATA-REC.
      MOVE 11 TO LEN.
      MOVE "STRING" TO REC-TYPE.
*
      SET TPNOBLOCK TO TRUE.
      SET TPNOTIME TO TRUE.
      SET TPSIGRSTR TO TRUE.

```

```

*
MOVE SPACES TO LMID.
MOVE SPACES TO USERNAME.
MOVE SPACES TO CLTNAME.

Broadcasting Messages by Identifier

The [TPNOTIFY\(3cbl\)](#) routine is used to broadcast a message using an identifier received with a previously processed message. It can be called only from a service.

Use the following signature to call the TPNOTIFY routine:

```

01 TPSVCDEF-REC.
   COPY TPSVCDEF.
01 TPTYPE-REC.
   COPY TPTYPE.
01 DATA-REC.
   COPY User Data.
01 TPSTATUS-REC.
   COPY TPSTATUS.
CALL "TPNOTIFY" USING TPSVCDEF-REC TPTYPE-REC DATA-REC TPSTATUS-REC.

```

Refer to [“Writing Global Transactions”](#) in *Programming Oracle Tuxedo ATMI Applications Using C* for information on the TPSVCDEF-REC data structure, and [“Defining a Service”](#) in *Programming Oracle Tuxedo ATMI Applications Using C* for a description of the TPTYPE-REC record.

Checking for Unsolicited Messages

To check for unsolicited messages while running the client in “dip-in” notification mode, use the [TPCHKUNSOL\(3cbl\)](#) routine with the following signature:

```

01 MSG-NUM          PIC S9(9)  COMP-5.
01 TPSTATUS-REC.

```

```

COPY TPSTATUS.
CALL "TPCHKUNSOL" USING MSG-NUM TPSTATUS-REC.

```

If any messages are pending, the system invokes the unsolicited message handling routine that was specified using TPSETUNSOL. Upon completion, the routine returns either the number of unsolicited messages that were processed and sets TP-STATUS to [TPOK].

If you issue this routine when the client is running in SIGNAL-based, thread-based notification mode, or is ignoring unsolicited messages, the routine has no impact and returns immediately.

The following example shows how to check for the arrival of an unsolicited message.

Listing 8-3 Arrival of an Unsolicited Message

```

*
* Check for unsolicited messages
*
CALL "TPCHKUNSOL" USING MESS-NUM
                        TPSTATUS-REC.
*
IF TPOK
    IF MESS-NUM IS = 0
        No messages were processed by the
        unsolicited routine
    ELSE
        MESS-NUM number of messages were
        processed by the unsolicited routine
    END-IF
ELSE
    process error
END-IF

```

Getting Unsolicited Messages

To get unsolicited messages, you must call the `TPGETUNSOL(3cbl)` routine. This routine can be called, however, only from an unsolicited message handler. Use the following signature to call the `TPGETUNSOL` routine:

```
01 TPTYPE-REC.  
   COPY TPTYPE.  
01 DATA-REC.  
   COPY User data.  
01 TPSTATUS-REC.  
   COPY TPSTATUS.  
CALL "TPGETUNSOL" USING TPTYPE-REC DATA-REC TPSTATUS-REC.
```

Refer to “[Defining a Service](#)” in *Programming Oracle Tuxedo ATMI Applications Using C* for a description of the `TPTYPE-REC` record.

The following example shows how to get an unsolicited message.

Listing 8-4 Getting an Unsolicited Message

Subscribing to Events

The [TPSUBSCRIBE \(3cb1\)](#) routine enables an Oracle Tuxedo system ATMI client or server to subscribe to an event.

A subscriber can be notified through an unsolicited notification message, a service call, a reliable queue, or other notification methods configured by the application administrator. (For information about configuring alternative notification methods, refer to *Setting Up an Oracle Tuxedo Application*.)

Use the following signature to call the TPSUBSCRIBE routine:

```

01  TPEVTDEF-REC .
    COPY TPEVTDEF.

01  TPQUEDEF-REC .
    COPY TPQUEDEF.

```

```

01 TPSTATUS-REC.
   COPY TPSTATUS.

CALL "TPSUBSCRIBE" USING TPEVTDEF-REC TPQUEDEF-REC TPSTATUS-REC

```

The TPEVTDEF-REC data structure signature is as follows:

```

05 TPBLOCK-FLAG      PIC S9(9) COMP-5.
   88 TPBLOCK        VALUE 0.
   88 TPNOBLOCK      VALUE 1.
05 TPTRAN-FLAG       PIC S9(9) COMP-5.
   88 TPTRAN         VALUE 0.
   88 TPNOTRAN       VALUE 1.
05 TPREPLY-FLAG      PIC S9(9) COMP-5.
   88 TPREPLY        VALUE 0.
   88 TPNOREPLY      VALUE 1.
05 TPTIME-FLAG       PIC S9(9) COMP-5.

   88 TPEVNOPERSIST  VALUE 0.
   88 TPEVPERSIST    VALUE 1.
05 TPEV-TRAN-FLAG    PIC S9(9) COMP-5.
   88 TPEVNOTRAN     VALUE 0.
   88 TPEVTRAN       VALUE 1.
*
05 EVENT-COUNT       PIC S9(9) COMP-5.
05 SUBSCRIPTION-HANDLE PIC S9(9) COMP-5.
05 NAME-1            PIC X(127).
05 NAME-2            PIC X(127).
05 EVENT-NAME        PIC X(31).
05 EVENT-EXPR        PIC X(255).
05 EVENT-FILTER       PIC X(255).

```

The following table describes the members of the TPEVTDEF-REC data structure.

Member	Description
EVENT-COUNT	Event count.
SUBSCRIPTION-HANDLE	Subscription handle.
NAME-1, NAME-2	Name of queued spaces. If the subscriber sets TPEVQUEUE, then event notifications are enqueued to the queue space named by NAME-1 and the queue named by NAME-2.
EVENT-NAME	Event name.
EVENT-EXPR	<p>Set of events to which to subscribe. Consists of a null-terminated string of up to 255 characters containing a regular expression. Regular expressions are of the form specified in tpssubscribe(3c) as described in the <i>Programming Oracle Tuxedo ATMI Applications Using C</i>. For example, if eventexpr is set to:</p> <ul style="list-style-type: none"> "\ . *" — the caller is subscribing to all system-defined events. "\ . SysServer . *" — the caller is subscribing to all system-defined events related to servers. " [A-Z] . *" — the caller is subscribing to all user events starting with A-Z. ". * (ERR err) . *" — the caller is subscribing to all user events containing either the substring ERR or the substring err (for example, account_error and ERROR_STATE events would both qualify).

Member	Description
EVENT-FILTER	<p>String containing a Boolean filter rule that must be evaluated successfully before the Event Broker posts the event. Upon receiving an event to be posted, the Event Broker applies the filter rule, if one exists, to the posted event's data. If the data passes the filter rule, the Event Broker invokes the notification method specified; otherwise, the Event Broker ignores the notification method. The caller can subscribe to the same event multiple times with different filter rules.</p> <p>By using the event filtering capability, subscribers can be more discriminating about the events for which they are notified. For example, a poster can post an event for withdrawals greater than \$10,000.00, but a subscriber may want to specify a higher threshold for being notified, such as \$50,000.00. Or, a subscriber may want to be notified of large withdrawals only if made by customers with specified IDs.</p> <p>Filter rules are specific to the typed records to which they are applied. Refer to the TPSUBSCRIBE (3cb1) reference page in the <i>Oracle Tuxedo ATMI COBOL Function Reference</i> for further information on filter rules.</p>
SETTINGS (TPBLOCK-FLAG, TPTRAN-FLAG, and so on)	<p>Miscellaneous settings that control the server characteristics. For more information on the settings, refer to the <i>Oracle Tuxedo ATMI COBOL Function Reference</i>.</p>

Refer to *Using the ATMI/Q Component* for more information on the TPQUEDEF-REC data structure.

You can subscribe to both system- and application-defined events using the TPSUBSCRIBE routine.

For purposes of subscriptions (and for MIB updates), service routines executed in an Oracle Tuxedo system server process are considered to be trusted code.

Refer to [TPSUBSCRIBE \(3cb1 \)](#) in the *Oracle Tuxedo ATMI COBOL Function Reference* for more information on the routine.

Unsubscribing from Events

The `TPUNSUBSCRIBE(3cbl)` routine enables an Oracle Tuxedo system ATMI client or server to unsubscribe from an event.

Use the following signature to call the `TPUNSUBSCRIBE` routine:

```
01  TPEVTDEF-REC .
    COPY TPEVTDEF .

01  TPSTATUS-REC .
    COPY TPSTATUS .

CALL "TPUNSUBSCRIBE" USING TPEVTDEF-REC TPSTATUS-REC
```

Refer to [“Subscribing to Events” on page 8-11](#) for a detailed description of the `TPEVTDEF-REC` data structure, and to *Using the ATMI/Q Component* for more information on the `TPQUEDEF-REC` data structure.

Posting Events

The `TPPOST(3cbl)` routine enables an Oracle Tuxedo ATMI client or server to post an event.

Use the following signature to call the `TPPOST` routine:

```
01  TPEVTDEF-REC .
    COPY TPEVTDEF .

01  TPTYPE-REC .
    COPY TPSTATUS .

01  TPDATA-REC .
    COPY TPSTATUS .

01  TPSTATUS-REC .
    COPY TPSTATUS .

CALL "TPPOST" USING TPEVTDEF-REC TPTYPE-REC TPDATA-REC TPSTATUS-REC
```

Refer to [“Subscribing to Events” on page 8-11](#) for a detailed description of the `TPEVTDEF-REC` data structure, and to [“Defining a Service”](#) in *Programming Oracle Tuxedo ATMI Applications Using C* for a description of the `TPTYPE-REC` record.

Writing Global Transactions

This topic includes the following sections:

- [What Is a Global Transaction?](#)
- [Starting the Transaction](#)
- [Terminating the Transaction](#)
- [Terminating the Transaction](#)
- [Implicitly Defining a Global Transaction](#)
- [Defining Global Transactions for an XA-Compliant Server Group](#)
- [Testing Whether a Transaction Has Started](#)

What Is a Global Transaction?

A global transaction is a mechanism that allows a set of programming tasks, potentially using more than one resource manager and potentially executing on multiple servers, to be treated as one logical unit.

Once a process is in transaction mode, any service requests made to servers may be processed on behalf of the current transaction. The services that are called and join the transaction are referred to as *transaction participants*. The value returned by a participant may affect the outcome of the transaction.

A global transaction may be composed of several local transactions, each accessing the same resource manager. The resource manager is responsible for performing concurrency control and atomicity of updates. A given local transaction may be either successful or unsuccessful in completing its access; it cannot be partially successful.

A maximum of 16 server groups can participate in a single transaction.

The Oracle Tuxedo system manages a global transaction in conjunction with the participating resource managers and treats it as a specific sequence of operations that is characterized by atomicity, consistency, isolation, and durability. In other words, a global transaction is a logical unit of work in which:

- All portions either succeed or have no effect.
- Operations are performed that correctly transform resources from one consistent state to another.
- Intermediate results are not accessible to other transactions, although some processes in a transaction may access the data associated with another process.
- Once a sequence is complete, its results cannot be altered by any kind of failure.

The Oracle Tuxedo system tracks the status of each global transaction and determines whether it should be committed or rolled back.

Starting the Transaction

To start a global transaction, use the `TPBEGIN(3cbl)` routine with the following signature:

```
*
01  TPTRXDEF-REC .
    COPY  TPTRXDEF .
*
01  TPSTATUS-REC .
    COPY  TPSTATUS .
*
CALL  "TPBEGIN"  USING  TPTRXDEF-REC  TPSTATUS-REC .
```

[Table 9-1](#) describes the `TPTRXDEF-REC` structure fields

Table 9-1 TPTRXDEF Structure Field

Field	Description
T-OUT	<p>Specifies the amount of time, in seconds, a transaction can execute before timing out. You can set this value to the maximum number of seconds allowed by the system, by specifying a value of 0. In other words, you can set <i>timeout</i> to the maximum value for an unsigned <code>long</code> as defined by the system.</p> <p>The use of 0 or an unrealistically large value for the T-OUT parameter delays system detection and reporting of errors. The system uses the T-OUT parameter to ensure that responses to service requests are sent within a reasonable time, and to terminate transactions that encounter problems such as network failures before executing a commit.</p> <p>For a transaction in which a person is waiting for a response, you should set this parameter to a small value: if possible, less than 30 seconds.</p> <p>In a production system, you should set T-OUT to a value large enough to accommodate expected delays due to system load and database contention. A small multiple of the expected average response time is often an appropriate choice.</p> <p>Note: The value assigned to the T-OUT parameter should be consistent with that of the SCANUNIT parameter set by the Oracle Tuxedo application administrator in the configuration file. The SCANUNIT parameter specifies the frequency with which the system checks, or <i>scans</i>, for timed-out transactions and blocked calls in service requests. The value of this parameter represents the interval of time between these periodic scans, referred to as the <i>scanning unit</i>.</p> <p>You should set the T-OUT parameter to a value that is greater than the scanning unit. If you set the T-OUT parameter to a value smaller than the scanning unit, there will be a discrepancy between the time at which a transaction times out and the time at which this timeout is discovered by the system. The default value for SCANUNIT is 10 seconds. You may need to discuss the setting of the T-OUT parameter with your application administrator to make sure the value you assign to the T-OUT parameter is compatible with the values assigned to your system parameters.</p>
TRANID	Transaction identifier.

Any process may call `TPBEGIN` unless the process is already in transaction mode. If `TPBEGIN` is called in transaction mode, the call fails due to a protocol error and `TP-STATUS` is set to `TPEPROTO`. If the process is in transaction mode, the transaction is unaffected by the failure.

The following example provides a high-level view of how a global transaction is defined.

Listing 9-1 Delineating a Transaction

```
. . .
MOVE 0 TO T-OUT.
CALL "TPBEGIN" USING
    TPTRXDEF-REC
    TPSTATUS-REC.
IF NOT TPOK
    error processing
. . .
    program statements
. . .
CALL "TPCOMMIT" USING
    TPTRXDEF-REC
    TPSTATUS-REC.
IF NOT TPOK
    error processing
```

The following example shows how an outstanding reply can cause an error.

Listing 9-2 Error - Starting a Transaction with an Outstanding Reply

```
. . .
MOVE "BUY" TO SERVICE-NAME.
SET TPBLOCK TO TRUE.
SET TPNOTRAN TO TRUE.
SET TPREPLY TO TRUE.
SET TPNOTIME TO TRUE.
```

```

SET TPSIGRSTRT TO TRUE.
CALL "TPACALL" USING
    TPSVCDEF-REC
    TPTYPE-REC
    BUY-REC
    TPSTATUS-REC.

IF NOT TPOK
    error processing
    . . .
MOVE 0 TO T-OUT.
CALL "TPBEGIN" USING
    TPTRXDEF-REC
    TPSTATUS-REC.
vIF NOT TPOK
    error processing
* ERROR TP-STATUS is set to TPEPROTO
    . . .
    program statements
    . . .
SET TPBLOCK TO TRUE.
SET TPNOTRAN TO TRUE.
SET TPCHANGE TO TRUE.
SET TPNOTIME TO TRUE.
SET TPSIGRSTRT TO TRUE.
SET TPGETANY TO TRUE.
CALL "TPGETRPLY" USING
    TPSVCDEF-REC
    TPTYPE-REC
    WK-AREA
    TPSTATUS-REC.

IF NOT TPOK
    error processing

```

If a transaction times out, a call to TPCOMMIT causes the transaction to be aborted. As a result, TPCOMMIT fails and sets TP-STATUS to TPEABORT.

The following example shows how to test for a transaction timeout. Note that the value of T-OUT is set to 30 seconds.

Listing 9-3 Testing for Transaction Timeout

```
. . .
MOVE 30 TO T-OUT.
CALL "TPBEGIN" USING TPTRXDEF-REC TPSTATUS-REC.
IF NOT TPOK
    MOVE "Failed to BEGIN a transaction" TO LOG-REC-TEXT.
    MOVE 29 to LOG-REC-LEN
    CALL "USERLOG" USING
        LOG-REC-TEXT
        LOG-REC-LEN
        TPSTATUS-REC
    CALL "TPTERM" USING
        TPSTATUS-REC
    PERFORM A-999-EXIT.
. . .
    communication CALL statements
. . .
IF TPETIME
    CALL "TPABORT" USING
        TPTRXDEF-REC
        TPSTATUS-REC
IF NOT TPOK
    error processing
ELSE
    CALL "TPCOMMIT" USING
        TPTRXDEF-REC
        TPSTATUS-REC
    IF NOT TPOK
        error processing
```

Note: When a process is in transaction mode and makes a communication call with `TPNOTRAN`, it prohibits the called service from becoming a participant in the current transaction. Whether the service request succeeds or fails has no impact on the outcome of the transaction. The transaction can still timeout while waiting for a reply that is due from a service, whether it is part of the transaction or not. Refer to [“Managing Errors”](#) in *Programming Oracle Tuxedo ATMI Applications Using C* for more information on the effects of the `TPNOTRAN` flag.

The following example shows how to define a transaction.

Listing 9-4 Defining a Transaction

    EXIT PROGRAM.

```

Terminating the Transaction

To end a global transaction, call `TPCOMMIT(3cb1)` to commit the current transaction, or `TPABORT(3cb1)` to abort the transaction and roll back all operations.

Note: If `TPCALL`, `TPACALL`, or `TPCONNECT` is called by a process that has explicitly set `TPNOTRAN`, the operations performed by the called service do not become part of the current transaction. In other words, when you call the `TPABORT` routine, the operations performed by these services are not rolled back.

Committing the Current Transaction

The `TPCOMMIT(3cbl)` routine commits the current transaction. When `TPCOMMIT` returns successfully, all changes to resources as a result of the current transaction become permanent.

Use the following signature to call the `TPCOMMIT` routine:

```
*
01  TPTRXDEF-REC .
    COPY  TPTRXDEF.
*
01  TPSTATUS-REC .
    COPY  TPSTATUS.
*
CALL "TPCOMMIT" USING TPTRXDEF-REC TPSTATUS-REC.
```

Refer to [“Starting the Transaction” on page 9-2](#) for a description of the `TPTRXDEF-REC` structure.

Prerequisites for a Transaction Commit

For `TPCOMMIT` to succeed, the following conditions must be true:

- The calling process must be the same one that initiated the transaction with a call to `TPBEGIN`.
- The calling process must have no transactional replies (calls made without the `TPNOTRAN` flag) outstanding.
- The transaction must not be in a rollback-only state and must not be timed out.

If the first condition is false, the call fails and `TP-STATUS` is set to `TPEPROTO`, indicating a protocol error. If the second or third condition is false, the call fails and `TP-STATUS` is set to `TPEABORT`, indicating that the transaction has been rolled back. If `TPCOMMIT` is called by the initiator with outstanding transaction replies, the transaction is aborted and those reply descriptors associated with the transaction become invalid. If a participant calls `TPCOMMIT` or `TPABORT`, the transaction is unaffected.

A transaction is placed in a rollback-only state if any service call returns `TPFAIL` or indicates a service error. If `TPCOMMIT` is called for a rollback-only transaction, the routine cancels the transaction, returns -1, and sets `TP-STATUS` to `TPEABORT`. The results are the same if `TPCOMMIT` is called for a transaction that has already timed out: `TPCOMMIT` returns -1 and sets `TP-STATUS` to `TPEABORT`. Refer to “[Managing Errors](#)” in *Programming Oracle Tuxedo ATMI Applications Using C* for more information on transaction errors.

Two-phase Commit Protocol

When the `TPCOMMIT` routine is called, it initiates the *two-phase commit protocol*. This protocol, as the name suggests, consists of two steps:

1. Each participating resource manager indicates a readiness to commit.
2. The initiator of the transaction gives permission to commit to each participating resource manager.

The commit sequence begins when the transaction initiator calls the `TPCOMMIT` routine. The Oracle Tuxedo TMS server process in the designated coordinator group contacts the TMS in each participant group that is to perform the first phase of the commit protocol. The TMS in each group then instructs the resource manager (RM) in that group to commit using the XA protocol that is defined for communications between the Transaction Managers and RMs. The RM writes, to stable storage, the states of the transaction before and after the commit sequence, and indicates success or failure to the TMS. The TMS then passes the response back to the coordinating TMS.

When the coordinating TMS has received a success indication from all groups, it logs a statement to the effect that a transaction is being committed and sends second-phase commit notifications to all participant groups. The RM in each group then finalizes the transaction updates.

If the coordinator TMS is notified of a first-phase commit failure from any group, or if it fails to receive a reply from any group, it sends a rollback notification to each RM and the RMs back out all transaction updates. `TPCOMMIT` then fails and sets `TP-STATUS` to `TPEABORT`.

Selecting Criteria for a Successful Commit

When more than one group is involved in a transaction, you can specify which of two criteria must be met for `TPCOMMIT` to return successfully:

- When all participants have indicated a readiness to commit (that is, when all participants have reported that phase 1 of the two-phase commit has been logged as complete and the coordinating TMS has written its decision to commit to stable storage)
- When all participants have finished phase 2 of the two-phase commit

To specify one of these prerequisites, set the `CMTRET` parameter in the `RESOURCES` section of the configuration file to one of the following values:

- `LOGGED`—to require completion of phase 1
- `COMPLETE`—to require completion of phase 2

By default, `CMTRET` is set to `COMPLETE`.

Trade-offs Between Possible Commit Criteria

In most cases, when all participants in a global transaction have logged successful completion of phase 1, they do not fail to complete phase 2. By setting `CMTRET` to `LOGGED`, you allow a slightly faster return of calls to `TCOMMIT`, but you run the slight risk that a participant may heuristically complete its part of the transaction in a way that is not consistent with the commit decision.

Whether it is prudent to accept the risk depends to a large extent on the nature of your application. If your application demands complete accuracy (for example, if you are running a financial application), you should probably wait until all participants fully complete the two-phase commit process before returning. If your application is more time-sensitive, you may prefer to have the application execute faster at the expense of accuracy.

Aborting the Current Transaction

Use the [TPABORT\(3cbl\)](#) routine to indicate an abnormal condition and explicitly abort a transaction. This function invalidates the call descriptors of any outstanding transactional replies. None of the changes produced by the transaction are applied to the resource. Use the following signature to call the `TPABORT` routine:

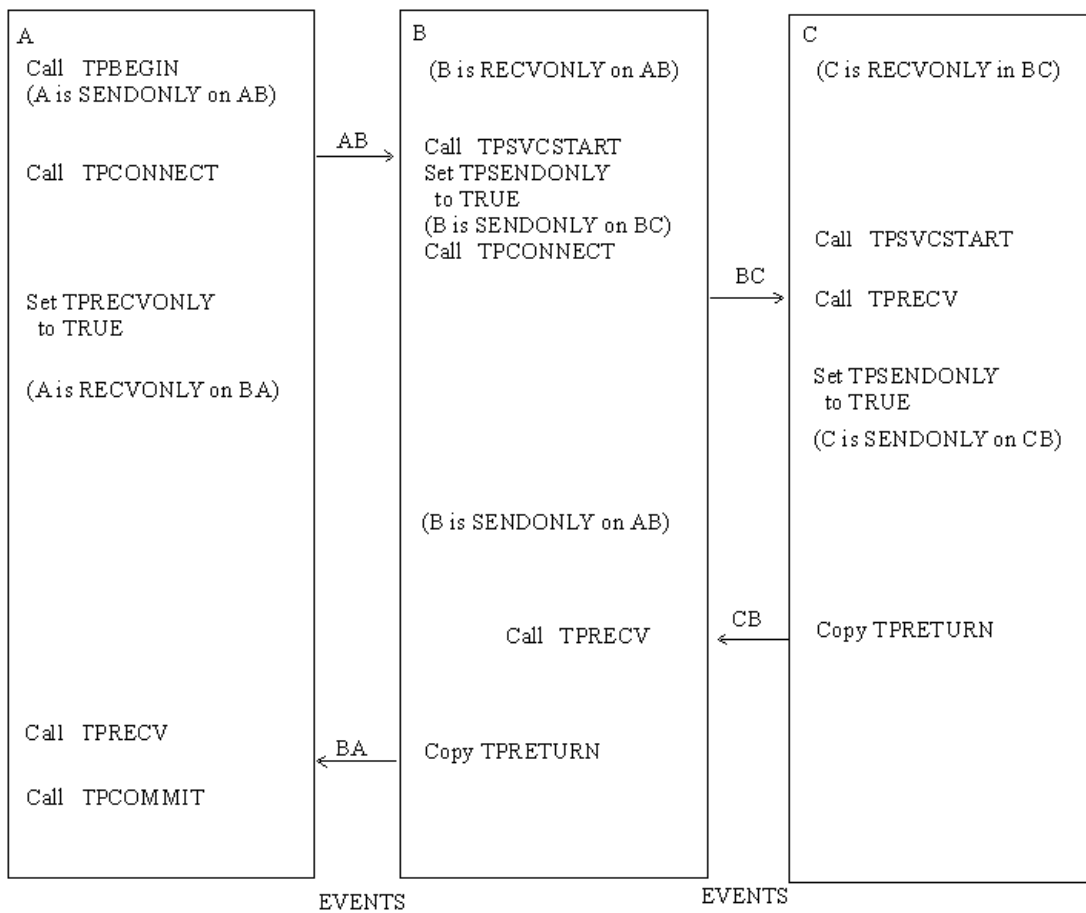

```
*
01  TPTRXDEF-REC .
    COPY TPTRXDEF.
*
01  TPSTATUS-REC .
    COPY TPSTATUS.
*
CALL "TPABORT" USING TPTRXDEF-REC TPSTATUS-REC.
```

Refer to [“Starting the Transaction” on page 9-2](#) for a description of the `TPTRXDEF-REC` structure.

Example: Committing a Transaction in Conversational Mode

Figure 9-1 illustrates a conversational connection hierarchy that includes a global transaction.

Figure 9-1 Connection Hierarchy in Transaction Mode

The connection hierarchy is created through the following process:

1. A client (process A) initiates a connection in transaction mode by calling `TPBEGIN` and `TPCONNECT`.

2. The client calls subsidiary services, which are executed.
3. As each subordinate service completes, it sends a reply indicating success or failure (TPEV_SVCSUCC or TPEV_SVCFAIL, respectively) back up through the hierarchy to the process that initiated the transaction. In this example the process that initiated the transaction is the client (process A). When a subordinate service has completed sending replies (that is, when no more replies are outstanding), it must call TPRETURN.
4. The client (process A) determines whether all subordinate services have returned successfully.
 - If so, the client commits the changes made by those services, by calling TPCOMMIT, and completes the transaction.
 - If not, the client calls TPABORT, since it knows that TPCOMMIT could not be successful.

Example: Testing for Participant Errors

In the following sample code, a client makes a synchronous call to the fictitious REPORT service (line 24). Then the code checks for participant failures by testing for errors that can be returned on a communication call (lines 30-42).

Listing 9-5 Testing for Participant Success or Failure

```

01  . . .
02  CALL "TPINITIALIZE" USING TPINFDEF-REC
03  USR-DATA-REC
04  TPSTATUS-REC.
05  IF NOT TPOK
06      error message,
07      EXIT PROGRAM .
08  MOVE 30 TO T-OUT.
09  CALL "TPBEGIN" USING TPTRXDEF-REC TPSTATUS-REC.
10  IF NOT TPOK
11      error message,
12      PERFORM DO-TPTERM.
13  * Set up record
14  MOVE "REPORT=accrcv DBNAME=accounts" TP-RECORD.
15  MOVE 27 TO LEN.
16  MOVE "REPORTS" TO SERVICE-NAME.
17  MOVE "STRING" TO REC-TYPE.
18  SET TPBLOCK TO TRUE.
19  SET TPTRAN IN TPSVCDEF-REC TO TRUE.
20  SET TPNOTIME TO TRUE.

```

```

21  SET TPSIGRSTRT TO TRUE.
22  SET TPCHANGE TO TRUE.
23  *
24  CALL "TPCALL" USING TPSVCDEF-REC
25                      TPTYPE-REC
26                      TP-RECORD
27                      TPTYPE-REC
28                      TP-RECORD
29                      TPSTATUS-REC.
30  IF  TPOK
31      PERFORM DO-TPCOMMIT
32      PERFORM DO-TPTERM.
33  * Check return status
34  IF  TPESVCERR
35      DISPLAY "REPORT service's TPRETURN encountered problems"
36  ELSE IF  TPESVCFAIL
37      DISPLAY "REPORT service FAILED with return code=" APPL-RETURN-CODE
38  ELSE IF  TPEOTYPE
39      DISPLAY "REPORT service's reply is not of any known REC-TYPE"
40  *
41  PERFORM DO-TPABORT
42  PERFORM DO-TPTERM.
43  * Commit global transaction
44  DO-TPCOMMIT.
45  CALL "TPCOMMIT" USING TPTRXDEF-REC
46                      TPSTATUS-REC
47  IF  NOT TPOK
48      error message
49  * Abort the transaction
50  DO-TPABORT.
51  CALL "TPABORT" USING TPTRXDEF-REC
52                      TPSTATUS-REC
53  IF  NOT TPOK
54      error message
55  * Leave the application
56  DO-TPTERM.
57  CALL "TPTERM" USING TPSTATUS-REC.
58  IF  NOT TPOK
59      error message
60  EXIT PROGRAM.

```

Implicitly Defining a Global Transaction

An application can start a global transaction in either of two ways:

- Explicitly, by calling ATMI calls, as described in [“Starting the Transaction” on page 9-2](#).

- Implicitly, from within a service routine

This section describes the second method.

You can implicitly place a service routine in transaction mode by setting the system parameter `AUTOTRAN` in the configuration file. If you set `AUTOTRAN` to `Y`, the system automatically starts a transaction in the service subroutine when a request is received from another process.

When implicitly defining a transaction, observe the following rules:

- If a process requests a service from another process when the calling process is *not* in transaction mode and the `AUTOTRAN` system parameter is set to start a transaction, the system initiates a transaction.
- If a process that is already in transaction mode requests a service from another process, the system's first response is to determine whether or not the caller is set to `TPNOTRAN`.

If not set to `TPNOTRAN`, then the system places the called process in transaction mode through the "rule of propagation." The system does not check the `AUTOTRAN` parameter.

If `TPTRN-FLAG` IN `TPSVCDEF-REC` is set to `TPNOTRAN`, the services performed by the called process are not included in the current transaction (that is, the propagation rule is suppressed). The system checks the `AUTOTRAN` parameter.

- If `AUTOTRAN` is set to `N` (or if it is not set), the system does not place the called process in transaction mode.
- If `AUTOTRAN` is set to `Y`, the system places the called process in transaction mode, but treats it as a new transaction.

Note: Because a service can be placed in transaction mode automatically, it is possible for a service with the `TPNOTRAN` flag set to call services that have the `AUTOTRAN` parameter set. If such a service requests another service, the member of the service information structure returns `TPTRAN` when queried. For example, if the call is made with `TPNOTRAN | TPNOREPLY`, and the service automatically starts a transaction when called, the information structure is set to `TPTRAN | TPNOREPLY`.

Defining Global Transactions for an XA-Compliant Server Group

Generally, the application programmer writes a service that is part of an XA-compliant server group to perform some operation via the group's resource manager. In the normal case, the service expects to perform all operations within a transaction. If, on the other hand, the service is

called with the communication setting of `TPNOTRAN`, you may receive unexpected results when executing database operations.

In order to avoid unexpected behavior, design the application so that services in groups associated with XA-compliant resource managers are always called in transaction mode or are always defined in the configuration file with `AUTOTRAN` set to `Y`. You should also test the transaction level in the service code early.

Testing Whether a Transaction Has Started

It is important to know whether or not a process is in transaction mode in order to avoid and interpret certain error conditions. For example, it is an error for a process already in transaction mode to call `TPBEGIN`. When `TPBEGIN` is called by such a process, it fails and sets `TP-STATUS` to `TPEPROTO` to indicate that it was invoked while the caller was already participating in a transaction. The transaction is not affected.

You can design a service subroutine so that it tests whether it is in transaction mode before invoking `TPBEGIN`. You can test the transaction level by either of the following methods:

- Querying the settings of the service information structure that is passed to the service routine. The service is in transaction mode if the value is set to `TPTRAN`.
- Calling the `TPGETLEV(3cbl)` routine.

Use the following signature to call the `TPGETLEV` routine:

```
01  TPTRXLEV-REC .  
    COPY TPTRXLEV .  
01  TPSTATUS-REC .  
    COPY TPSTATUS .  
CALL "TPGETLEV" USING TPTRXLEV-REC TPSTATUS-REC .
```

`TPGETLEV` returns `TP-NOT-IN-TRAN` if the caller is not in a transaction and `TP-IN-TRAN` if the caller is.

The following code sample shows how to test for transaction level using the `TPGETLEV` routine (line 3). If the process is not already in transaction mode, the application starts a transaction (line 5). If `TPBEGIN` fails, a message is returned to the status line (line 9) and `APPL-CODE IN TPSECRET-REC` of `TPRETURN` is set to a code that can be retrieved in `APL-RETURN-CODE IN TPSTATUS-REC` (lines 1 and 11).

Listing 9-6 Testing Transaction Level

```

    . . . Application defined codes
001      77 BEG-FAILED    PIC S9(9) VALUE 3.
    . . .
002  PROCEDURE DIVISION.
    . . .
003  CALL "TPGETLEV" USING TPTRCLEV-REC
                                TPSTATUS-REC.
004  IF NOT TPOK
        error processing  EXIT PROGRAM
005  IF TP-NOT-IN-TRAN
006      MOVE 30 TO T-OUT.
007      CALL "TPBEGIN" USING
                                TPTRXDEF-REC
                                TPSTATUS-REC.
008      IF NOT TPOK
009          MOVE "Attempt to TPBEGIN within service failed"
                                TO USER-MESSAGE.
010          SET TPFAIL TO TRUE.
011          MOVE BEG-FAILED TO APPL-CODE.
012          COPY TPRETURN REPLACING
013              DATA-REC BY USER-MESSAGE.
    . . .

```

If the AUTOTRAN parameter is set to Y, you do not need to call the TPBEGIN, and TPCOMMIT or TPABORT transaction routines explicitly. As a result, you can avoid the overhead of testing for transaction level. In addition, you can set the TRANTIME parameter to specify the time-out interval: the amount of time that may elapse after a transaction for a service begins, and before it is rolled back if not completed.

For example, suppose you are revising the OPEN_ACCT service shown in the preceding code listing. Currently, OPEN_ACCT defines the transaction explicitly and then tests for its existence. To reduce the overhead introduced by these tasks, you can eliminate them from the code. Therefore, you need to require that whenever OPEN_ACCT is called, it is called in transaction

mode. To specify this requirement, enable the AUTOTRAN and TRANTIME system parameters in the configuration file.

- [Planning and Designing a Multithreaded/Multicontexted ATMI Application](#)
- [Implementing a Multithreaded/ Multicontexted ATMI Application](#)
- [Testing a Multithreaded/Multicontexted ATMI Application](#)

Support for Programming a Multithreaded/Multicontexted ATMI Application

The Oracle Tuxedo system supports only:

- Kernel-level threads packages (user-level threads packages are not supported)
- Multithreaded applications written in C (multithreaded COBOL applications are not supported)
- Multicontexted applications written in either C or COBOL

If your operating system supports POSIX threads functions as well as other types of threads functions, we recommend using the POSIX threads functions, which make your code easier to port to other platforms later.

To find out whether your platform supports a kernel-level threads package, C functions, or POSIX functions, see the data sheet for your operating system in [Installing the Oracle Tuxedo System](#).

Platform-specific Considerations for Multithreaded/Multicontexted Applications

Many platforms have idiosyncratic requirements for multithreaded and multicontexted applications. [Installing the Oracle Tuxedo System](#) lists these platform-specific requirements. To find out what is needed on your platform, check the appropriate data sheet.

Planning and Designing a Multithreaded/Multicontexted ATMI Application

This topic includes the following sections:

- [What Are Multithreading and Multicontexting?](#)
- [Advantages and Disadvantages of a Multithreaded/Multicontexted ATMI Application](#)
- [How Multithreading and Multicontexting Work in a Client](#)
- [How Multithreading and Multicontexting Work in an ATMI Server](#)
- [Design Considerations for a Multithreaded and Multicontexted ATMI Application](#)

What Are Multithreading and Multicontexting?

The Oracle Tuxedo system allows you to use a single process to perform multiple tasks simultaneously. The programming techniques for implementing this sort of process usage are *multithreading* and *multicontexting*. This topic provides basic information about these techniques:

- [What Is Multithreading?](#)
- [What Is Multicontexting?](#)

What Is Multithreading?

Multithreading is the inclusion of more than one unit of execution in a single process. In a multithreaded application, multiple simultaneous calls can be made from the same process. For example, an individual process is not limited to one outstanding `tpcall(3c)`.

In a server, multithreading requires multicontexting except when application-created threads are used in a singled-context server. The only way to create a multithreaded, single-context application is to use application-created threads.

The Oracle Tuxedo system supports multithreaded applications written in C. It does not support multithreaded COBOL applications.

[Figure 10-1](#) shows how a multithreaded client can issue calls to three servers simultaneously.

Figure 10-1 Sample Multithreaded Process

In a multithreaded application, multiple service-dispatched threads are available in the same server, which means that fewer servers need to be started for that application.

Figure 10-2 shows how a server process can dispatch multiple threads to different clients simultaneously.

Figure 10-2 Multiple Service Threads Dispatched in One Server Process

What Is Multicontexting?

A context is an association to a domain. Multicontexting is the ability of a single process to have one of the following:

- More than one connection within a domain
- Connections to more than one domain

Multicontexting can be used in both clients and servers. When used in servers, multicontexting implies the use of multithreading, as well.

For a more complete list of the characteristics of a context, see “Context Attributes” in one of the following sections:

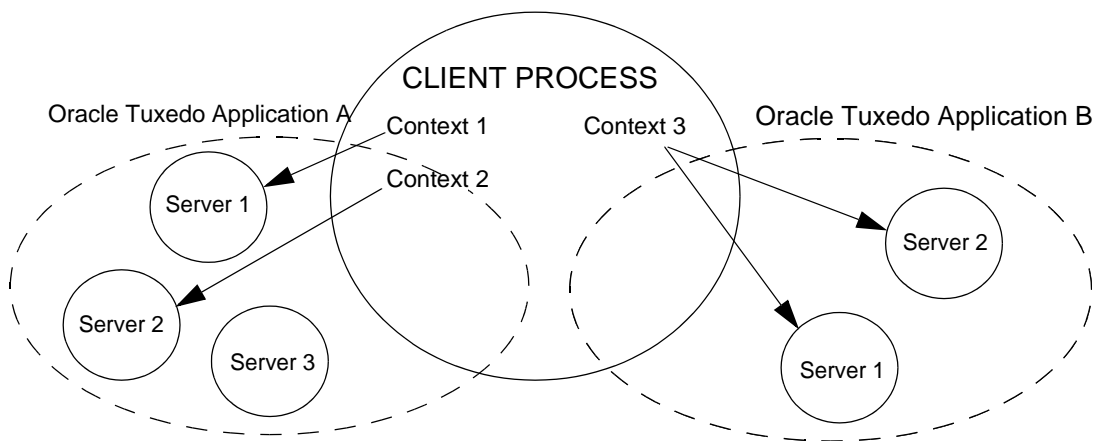

- [“Writing Code to Enable Multicontexting in an ATMI Client” on page 10-26](#)

- [“Writing Code to Enable Multicontexting and Multithreading in an ATMI Server” on page 10-33](#)

The Oracle Tuxedo system supports multicontexted applications written in either C or COBOL. Multithreaded applications, however, are supported only in C.

[Figure 10-3](#) shows how a multicontexted client process works within a domain. Each arrow represents an outstanding call to a server.

Figure 10-3 Multicontexted Process in Two Domains

Licensing a Multithreaded or Multicontexted Application

For licensing purposes, each context is counted as one user. Additional licenses are not required to accommodate multiple threads within one context. For example:

- If a process has two contexts associated with Application A and one with Application B, the Oracle Tuxedo system counts a total of three users (two in Application A and one in Application B).
- If a process has multiple threads accessing one application within the same context, the system counts only one user.

Advantages and Disadvantages of a Multithreaded/Multicontexted ATMI Application

Multithreading and multicontexting are powerful tools for enhancing the performance of Oracle Tuxedo applications—given the appropriate circumstances. Before embarking on a plan to use these techniques, however, it is important to understand potential benefits and pitfalls.

Advantages of a Multithreaded/Multicontexted ATMI Application

Multithreaded and multicontexted ATMI applications offer the following advantages:

- Improved performance and concurrency

For certain applications, performance and concurrency can be improved by using multithreading and multicontexting together. In other applications, performance can be unaffected or even degraded by using multithreading and multicontexting together. How performance is affected depends on your application.

- Simplified coding of remote procedure calls and conversations

In some applications it is easier to code different remote procedure calls and conversations in separate threads than to manage them from the same thread.

- Simultaneous access to multiple applications

Your Oracle Tuxedo clients can be connected to more than one application at a time.

- Reduced number of required servers

Because one server can dispatch multiple service threads, the number of servers to start for your application is reduced. This capability for multiple dispatched threads is especially useful for conversational servers, which otherwise must be dedicated to one client for the entire duration of a conversation.

For applications in which client threads are created by the Microsoft Internet Information Server API or the Netscape Enterprise Server interface (that is, the NSAPI), the use of multiple threads is essential if you want to obtain the full benefits afforded by these tools. This may be true of other tools, as well.

Disadvantages of a Multithreaded/Multicontexted ATMI Application

Multithreaded and multicontexted ATMI applications present the following disadvantages:

- **Difficulty of writing code**

Multithreaded and multicontexted applications are not easy to write. Only experienced programmers should undertake coding for these types of applications.

- **Difficulty of debugging**

It is much harder to replicate an error in a multithreaded or multicontexted application than it is to do so in a single-threaded, single-contexted application. As a result, it is more difficult, in the former case, to identify and verify root causes when errors occur.

- **Difficulty of managing concurrency**

The task of managing concurrency among threads is difficult and has the potential to introduce new problems into an application.

- **Difficulty of testing**

Testing a multithreaded application is more difficult than testing a single-threaded application because defects are often timing-related and more difficult to reproduce.

- **Difficulty of porting existing code**

Existing code often requires significant re-architecting to take advantage of multithreading and multicontexting. Programmers need to:

- Remove static variables
- Replace any function calls that are not thread-safe
- Replace any other code that is not thread-safe

Because the completed port must be tested and retested, the work required to port a multithreaded and/or multicontexted application is substantial.

How Multithreading and Multicontexting Work in a Client

When a multithreaded and multicontexted application is active, the life cycle of a client can be described in three phases:

- [Start-up Phase](#)
- [Work Phase](#)
- [Completion Phase](#)

Start-up Phase

In the start-up phase the following events occur:

- Some client threads join one or more Oracle Tuxedo applications by calling `tpinit(3c)`.
- Other client threads share the contexts created by the first set of threads by calling `tpsetctxt(3c)`.
- Some client threads join multiple contexts.
- Some client threads switch to an existing context.

Note: There may also be threads that work independently of the Oracle Tuxedo system. We do not consider such threads in this documentation.

Client Threads Join Multiple Contexts

A client in an Oracle Tuxedo multicontexted application can have more than one application association as long as the following rules are observed:

- All associations must be made to the same installation of the Oracle Tuxedo system.
- All application associations must be made from the same type of client. In other words, one of the following must be true:
 - All application associations must be made from native clients only.
 - All application associations must be made from Workstation clients only.

To join multiple contexts, clients call the `tpinit(3c)` function with the `TPMULTICONTEXTS` flag set in the `flags` element of the `TPINFO` data type.

When `tpinit()` is called with the `TPMULTICONTEXTS` flag set, a new application association is created and is designated the current association for the thread. The Oracle Tuxedo domain to

which the new association is made is determined by the value of the `TUXCONFIG` or `WSENVFILE/WSNADDR` environment variable.

Client Threads Switch to an Existing Context

Many ATMI functions operate on a per-context basis. (For a complete list, see [“Using Per-context Functions and Data Structures in a Multithreaded ATMI Client” on page 10-44.](#)) In such cases, the target context must be the current context. Although clients can join more than one context, at any time, in any thread, only one context can be the current context.

As task priorities shift within an application, requiring interactions with one Oracle Tuxedo domain rather than another, it is sometimes advantageous to reassign a thread from one context to another.

In such situations, one client thread calls `tpgetctxt(3c)` and passes the handle that is returned (the value of which is the current context) to a second client thread. The second thread then associates itself with the current context by calling `tpsetctxt(3c)` and specifying the handle it received from `tpgetctxt(3c)` via the first thread.

Once the second thread is associated with the desired context, it is available to perform tasks executed by ATMI functions that operate on a per-context basis. For details, see [“Using Per-context Functions and Data Structures in a Multithreaded ATMI Client” on page 10-44.](#)

Work Phase

In this phase each thread performs a task. The following is a list of sample tasks:

- A thread issues a request for a service.
- A thread gets the reply to a service request.
- A thread initiates and/or participates in a conversation.
- A thread begins, commits, or rolls back a transaction.

Service Requests

A thread sends a request to a server by calling either `tpcall(3c)` for a synchronous request or `tpacall(3c)` for an asynchronous request. If the request is sent with `tpcall()`, then the reply is received without further action by any thread.

Replies to Service Requests

If an asynchronous request for a service has been sent with `tpcall(3c)`, a thread in the same context (which may or may not be the same thread that sent the request) gets the reply by calling `tpgetrply(3c)`.

Transactions

If one thread starts a transaction, then all threads that share the context of that thread also share the transaction.

Many threads in a context may work on a transaction, but only one thread may commit or abort it. The thread that commits or aborts the transaction can be any thread working on the transaction; it is not necessarily the same thread that started the transaction. Threaded applications are responsible for providing appropriate synchronization so that the normal rules of transactions are followed. (For example, there can be no outstanding RPC calls or conversations when a transaction is committed, and no stray calls are allowed after a transaction has been committed or aborted.) A process may be part of at most one transaction for each of its application associations.

If one thread of an application calls `tpcommit(3c)` concurrently with an RPC or conversational call in another thread of the application, the system acts as if the calls were issued in some serial order. An application context may temporarily suspend work on a transaction by calling `tpsuspend(3c)` and then start another transaction subject to the same restrictions that exist for single-threaded and single-context programs.

Unsolicited Messages

For each context in a multithreaded or multicontexted application, you may choose one of three methods for handling unsolicited messages.

A context may . . .	By setting . . .
Ignore unsolicited messages	TPU_IGN
Use dip-in notification	TPU_DIP
Use dedicated thread notification. (available only for C applications)	TPU_THREAD

The following caveats apply:

- SIGNAL-based notification is not allowed in multithreaded or multicontexted processes.
- If your application runs on a platform that supports multicontexting but not multithreading, then you cannot use the `TPU_THREAD` unsolicited notification method. As a result, you cannot receive immediate notification of events.

If receiving immediate notification of events is important to your application, then you should carefully consider whether to use a multicontexted approach on this platform.

- Dedicated thread notification is available only:
 - For applications written in C
 - On multithreaded platforms supported by the Oracle Tuxedo system

When dedicated thread notification is chosen, the system dedicates a separate thread to receive unsolicited messages and dispatch the unsolicited message handler. Only one copy of the unsolicited message handler can run at any one time in a given context.

If `tpinit(3c)` is called on a platform for which the Oracle Tuxedo system does not support threads, with parameters indicating that `TPU_THREAD` notification is being requested on a platform that does not support threads, `tpinit()` returns `-1` and sets `tperrno` to `TPEINVAL`. If the `UBBCONFIG(5)` default `NOTIFY` option is set to `THREAD` but threads are not available on a particular machine, the default behavior for that machine is downgraded to `DIPIN`. The difference between these two behaviors allows an administrator to specify a default for all machines in a mixed configuration—a configuration that includes some machines that support threads and some that do not—but it does not allow a client to explicitly request a behavior that is not available on its machine.

If `tpsetunsol(3c)` is called from a thread that is not associated with a context, a per-process default unsolicited message handler for all new `tpinit(3c)` contexts created is established. A specific context may change the unsolicited message handler for that context by calling `tpsetunsol()` again when the context is active. The per-process default unsolicited message handler may be changed by again calling `tpsetunsol()` in a thread not currently associated with a context.

If a process has multiple associations with the same application, then each association is assigned a different `CLIENTID` so that it is possible to send an unsolicited message to a specific application association. If a process has multiple associations with the same application, then any `tpbroadcast(3c)` is sent separately to each of the application associations that meet the broadcast criteria. When performing a dip-in check for receiving unsolicited messages, an application checks for only those messages sent to the current application association.

In addition to the ATMI functions permitted in unsolicited message handlers, it is permissible to call `tpgetctxt(3c)` within an unsolicited message handler. This functionality allows an unsolicited message handler to create another thread to perform any more substantial ATMI work required within the same context.

Userlog Maintains Thread-specific Information

For each thread in each application, `userlog(3c)` records the following identifying information:

`process_ID.thread_ID.context_ID`

Placeholders are printed in the `thread_ID` and `context_ID` fields of entries for non-threaded platforms and single-contexted applications.

The `TM_MIB(5)` supports this functionality in the `TA_THREADID` and `TA_CONTEXTID` fields in the `T_ULOG` class.

Completion Phase

In this phase, when the client process is about to exit, on behalf of the current context and all associated threads, a thread ends its application association by calling `tpterm(3c)`. Like other ATMI functions, `tpterm()` operates on the current context. It affects all threads for which the context is set to the terminated context, and terminates any commonality of context among these threads.

A well-designed application normally waits for all work in a particular context to complete before it calls `tpterm()`. Be sure that all threads are synchronized before your application calls `tpterm()`.

How Multithreading and Multicontexting Work in an ATMI Server

The events that occur in an ATMI server when a multithreaded and multicontexted application is active can be described in three phases:

- [Start-up Phase](#)
- [Work Phase](#)
- [Completion Phase](#)

Start-up Phase

What happens during the start-up phase depends on the value of the `MINDISPATCHTHREADS` and `MAXDISPATCHTHREADS` parameters in the configuration file.

If the value of <code>MINDISPATCHTHREADS</code> is ...	And the value of <code>MAXDISPATCHTHREADS</code> is ...	Then ...
0	> 1	<ol style="list-style-type: none"> 1. The Oracle Tuxedo system creates a thread dispatcher. 2. The dispatcher calls <code>tpsvrinit(3c)</code> to join the application.
> 0	> 1	<ol style="list-style-type: none"> 1. The Oracle Tuxedo system creates a thread dispatcher. 2. The dispatcher calls <code>tpsvrinit(3c)</code> to join the application. 3. The Oracle Tuxedo system creates additional threads for handling service requests, and a context for each new thread. 4. Each new system-created thread calls <code>tpsvrthrinit(3c)</code> to join the application.

Work Phase

In this phase, the following activities occur:

- Multiple client requests to one server are handled concurrently in multiple contexts. The system allocates a separate thread for each request.
- If necessary, additional threads (up to the number indicated by `MAXDISPATCHTHREADS`) are created.
- The system keeps statistics on server threads.

Server-dispatched Threads Are Used

In response to clients' requests for a service, the server dispatcher creates multiple threads (up to a configurable maximum) in one server that can be assigned to various client requests concurrently. A server cannot become a client by calling `tpinit(3c)`.

Each dispatched thread is associated with a separate context. This feature is useful in conversational and RPC servers. It is especially useful for conversational servers which otherwise sit idle, waiting for the client side of a conversation while other conversational connections are waiting for service.

This functionality is controlled by the following parameters in the `SERVERS` section of the `UBBCONFIG(5)` file and the `TM_MIB(5)`.

UBBCONFIG Parameter	MIB Parameter	Default
<code>MINDISPATCHTHREADS</code>	<code>TA_MINDISPATCHTHREADS</code>	0
<code>MAXDISPATCHTHREADS</code>	<code>TA_MAXDISPATCHTHREADS</code>	1
<code>THREADSTACKSIZE</code>	<code>TA_THREADSTACKSIZE</code>	0 (representing the OS default)

- Each dispatched thread is created with the stack size specified by `THREADSTACKSIZE` (or `TA_THREADSTACKSIZE`). If this parameter is not specified or has a value of 0, the operating system default is used. On a few operating systems on which the default is too small to be used by the Oracle Tuxedo system, a larger default is used.
- If the value of this parameter is not specified or is 0, or if the operating system does not support setting a `THREADSTACKSIZE`, then the operating system default is used.
- `MINDISPATCHTHREADS` (or `TA_MINDISPATCHTHREADS`) must be less than or equal to `MAXDISPATCHTHREADS` (or `TA_MAXDISPATCHTHREADS`).

- If `MAXDISPATCHTHREADS` (or `TA_MAXDISPATCHTHREADS`) is 1, then the dispatcher thread and the service function thread are the same thread.
- If `MAXDISPATCHTHREADS` (or `TA_MAXDISPATCHTHREADS`) is greater than 1, any separate thread used for dispatching other threads does not count toward the limit of dispatched threads.
- Initially, the system boots `MINDISPATCHTHREADS` (or `TA_MINDISPATCHTHREADS`) server threads.
- The system never boots more than `MAXDISPATCHTHREADS` (or `TA_MAXDISPATCHTHREADS`) server threads.

Application-created Threads Are Used

Using your operating system functions, you may create additional threads within an application server. Application-created threads may:

- Operate independently of the Oracle Tuxedo system
- Operate in the same context as an existing server dispatch thread
- Perform work on behalf of server dispatch contexts

Some restrictions govern what you can do if you create threads in your application.

- Servers may not become clients by calling `tpinit(3c)`.
- Initially, application-created server threads are not associated with any server dispatch context. An application-created server thread may call `tpsetctxt(3c)` (and pass it a value returned by a previous call to `tpgetctxt(3c)` within a server-dispatched thread) to associate itself with that server-dispatched context.
- An application-created server thread cannot call `tpreturn(3c)` or `tpforward(3c)`. When an application-created server thread has finished its work, it must call `tpsetctxt(3c)` with the context set to `TPNULLCONTEXT` before the originally dispatched thread calls `tpreturn()`.

Bulletin Board Liaison Verifies Sanity of System Processes

The Bulletin Board Liaison (BBL) periodically checks servers. If a server is taking too long to execute a particular service request, the BBL kills that server. (If specified, the BBL then restarts the server.) If the BBL kills a multicontexted server, the other service calls that are currently being executed are also terminated as a result of the process being killed.

The BBL also sends a message to any process or thread that has been waiting longer than its timeout value to receive a message. The blocking message receive call then returns an error indicating a timeout.

System Keeps Statistics on Server Threads

For each server, the Oracle Tuxedo system maintains statistics for the following information:

- Maximum number of server-dispatched threads allowed
- Number of server-dispatched threads currently in use (TA_CURDISPATCHTHREADS)
- High-water mark of concurrent server-dispatched threads since the server was booted (TA_HWDISPATCHTHREADS)
- Number of server-dispatched threads historically started (TA_NUMDISPATCHTHREADS)

Userlog Maintains Thread-specific Information

For each thread in each application, `userlog(3c)` records the following identifying information:

process_ID.thread_ID.context_ID

Placeholders are printed in the *thread_ID* and *context_ID* fields of entries for non-threaded platforms and single-contexted applications.

The `TM_MIB(5)` supports this functionality in the TA_THREADID and TA_CONTEXTID fields in the T_ULONG class.

Completion Phase

When the application is shut down, `tpsvrthrdone(3c)` and `tpsvrdone(3c)` are called to perform any termination processing that is necessary, such as closing a resource manager.

Design Considerations for a Multithreaded and Multicontexted ATMI Application

Multithreaded and multicontexted ATMI applications are appropriate for some Oracle Tuxedo domains, but not all. To decide whether to create such applications, you should answer several basic questions about the following:

- Your development and run-time environments
- Design requirements for your application
- Type of threads model to use
- Interoperability restrictions for Workstation clients

Environment Requirements

When considering the development of multithreaded and/or multicontexted applications, examine the following aspects of your development and run-time environments:

- Do you have an experienced team of programmers capable of writing and debugging multithreaded and multicontexted programs that successfully manage concurrency and synchronization?
- Are the multithreading features of the Oracle Tuxedo system supported on the platform on which you are developing your application? These features are supported only on platforms with an OS-provided threads package, providing an appropriate level of functionality.
- Do the resource managers (RMs) used by your servers support multithreading? If so, consider the following issues, as well:
 - Do you need to set any parameters required by your RM to enable multithreaded access by your servers? For example, if you use an Oracle database with a multithreaded application, you must set the `THREADS=true` parameter as part of the `OPENINFO` string passed to Oracle. By doing so, you make it possible for individual threads to operate as separate Oracle associations.
 - Does your RM support a mixed mode of operation? A mixed-mode operation is a form of access such that multiple threads in a process can map to one RM association while other threads in the same process simultaneously map to different RM associations. Within one process, for example, Threads A and B map to RM Association X, while Thread C maps to RM Association Y.

Not all RMs support mixed-mode operation. Some require all threads in a given process to map to the same RM association. If you are designing an application that will make use of transactional RM access within application-created threads, make sure your RM supports mixed-mode operation.

Design Requirements

When designing a multithreaded and/or multicontexted application, you should consider the following design questions:

- Is the task performed by your application suitable for multithreading and/or multicontexting?
- Do you want to connect to more than one Oracle Tuxedo application? How many connections to each target application do you want?
- What synchronization issues need to be addressed in your application?
- Will you need to port your application to another platform after you have put your initial application into production?

Is the Task of Your Application Suitable for Multithreading and/or Multicontexting?

The following table provides a list of questions to help you decide whether your application would be improved if it were multithreaded and/or multicontexted. This list is not comprehensive; your individual requirements will determine other factors that should be considered.

For additional suggestions, we recommend that you consult a multithreaded and/or multicontexted programming publication.

If the answer to this question . . .	Is YES, then you might consider using . . .
Does your client need to connect to more than one application without using the Domains feature?	Multicontexting.
Does your client perform the role of a multiplexer within your application? For example, have you designated one machine in your application the “surrogate” for 100 other machines?	Multicontexting.

If the answer to this question . . .	Is YES, then you might consider using . . .
Does your client use multicontexting?	Multithreading. By allocating one thread per context, you can simplify your code.
Does your client perform two or more tasks that can be executed independently for a long time such that the performance gains from concurrent execution outweigh the costs and complexities of threads synchronization?	Multithreading.
Do you want one server to process multiple concurrent requests?	Multithreading. Assign a value greater than 1 to MAXDISPATCHTHREADS. This value enables multiple clients, each in its own thread, for the server.
If your client or server had multiple threads, would it be necessary to synchronize them after each thread had performed only a little work?	Not using multithreading.

How Many Applications and Connections Do You Want?

Decide how many applications you want to access and the number of connections you want to make.

- If you want connections to more than one application, then we recommend one of the following:
 - A single-threaded, multicontexted application
 - A multithreaded, multicontexted application
- If you want more than one connection to an application, then we recommend a multithreaded, multicontexted application.
- If you want only one connection to one application, then we recommend one of the following:
 - Multithreaded, single-contexted clients
 - Single-threaded, single-contexted clients

In both cases, multithreaded, multicontexted servers may be used.

What Synchronization Issues Need to Be Addressed?

This issue is an important one during the design phase. It is, however, beyond the scope of this documentation. Please refer to a publication about multithreaded and/or multicontexted programming.

Will You Need to Port Your Application?

If you may need to port your application in the future, you should keep in mind that different operating systems have different sets of functions. If you think you may want to port your application after completing the initial version of it on one platform, remember to consider the amount of staff time that will be needed to revise the code with a different set of functions.

Which Threads Model Is Best for You?

Various models for multithreaded programs are now being used, including the following:

- Boss/worker model
- Siblings model
- Workflow model

We do not discuss threads models in this documentation. We recommend that you research all available models and consider your design requirements carefully when choosing a programming model for your application.

Interoperability Restrictions for Workstation Clients

Interoperability between release 7.1 Workstation clients and applications based on pre-7.1 releases of the Oracle Tuxedo system is supported in any of the following situations:

- The client is neither multithreaded nor multicontexted.
- The client is multicontexted.
- The client is multithreaded and each thread is in a different context.

An Oracle Tuxedo Release 7.1 Workstation client with multiple threads in a single context cannot interoperate with a pre-7.1 release of the Oracle Tuxedo system.

Preliminary Guidelines for Programming a Multithreaded/Multicontexted ATMI Application

Before you start coding, make sure you have fulfilled or thought about the following:

- [“Prerequisites for a Multithreaded ATMI Application” on page 10-23](#)
- [“General Multithreaded Programming Considerations” on page 10-24](#)
- [“Concurrency Considerations” on page 10-24](#)

Prerequisites for a Multithreaded ATMI Application

Make sure your environment meets the following prerequisites before starting your development project.

- Your operating system must provide a suitable threads package supported by the Oracle Tuxedo system.

The Oracle Tuxedo system does not supply tools for creating threads, but it supports various threads packages provided by different operating systems. To create and synchronize threads, you must use the functions native to your operating system. To find out which, if any, threads packages are supported by your operating system, see [Installing the Oracle Tuxedo System](#).

- If you are using multithreaded servers, the resource managers used by those servers must support threads.

General Multithreaded Programming Considerations

Only experienced programmers should write multithreaded programs. In particular, programmers should already be familiar with basic design issues specific to this task, such as:

- The need for concurrency control among multiple threads
- The need to avoid the use of static variables in most instances
- Potential problems that may arise from the use of signals in multithreaded programs

These are just a few of the issues, too numerous to list here, with which we assume any programmer undertaking the writing of a multithreaded program is already familiar. These issues are discussed in many commercially available books on the subject of multithreaded programming.

Concurrency Considerations

Multithreading enables different threads of an application to perform concurrent operations on the same conversation. We do not recommend this approach, but the Oracle Tuxedo system does not forbid it. If different threads perform concurrent operations on the same conversation, the system acts as if the concurrent calls were issued in some arbitrary order.

When programming with multiple threads, you must manage the concurrency among them by using mutexes or other concurrency-control functions. Here are three examples of the need for concurrency control:

- When multithreaded threads are operating on the same context, the programmer must ensure that functions are being executed in the required serial order. For example, all RPC calls and conversations must be compiled before `tpcommit(3c)` can be called. If `tpcommit()` is called from a thread other than the thread from which all these RPC or

conversational calls are made, some concurrency control is probably required in the application.

- Similarly, it is permissible to call `tpacall(3c)` in one thread and `tpgetrply(3c)` in another, but the application must either:
 - Ensure that `tpacall()` is called before `tpgetrply()`, or
 - Manage the consequences if `tpacall()` is not called before `tpgetrply()`
- Multiple threads may operate on the same conversation but application programmers must realize that if different threads issue `tpsend(3c)` at approximately the same time, the system acts as though these `tpsend()` calls have been issued in an arbitrary order.

For most applications, the best strategy is to code all the operations for one conversation in one thread. The second best strategy is to serialize these operations using concurrency control.

- “Writing Code to Enable Multicontexting in an ATMI Client” on page 10-26
- “Writing Code to Enable Multicontexting and Multithreading in an ATMI Server” on page 10-33
- “Writing a Multithreaded ATMI Client” on page 10-38
- “Writing a Multithreaded ATMI Server” on page 10-50

Writing Code to Enable Multicontexting in an ATMI Client

To enable multicontexting in a client, you must write code that:

- Sets up multicontexting at initialization time
- Implements security
- If multithreading is also being used, synchronizes threads
- Switches contexts
- Handles unsolicited messages for each context

If your application uses transactions, you should also keep in mind the consequences of multicontexting for transactions. For more information, see [“Coding Rules for Transactions in a Multithreaded/Multicontexted ATMI Application” on page 10-32](#).

Note: The instructions and sample code provided in this section refer to the C library functions provided by the Oracle Tuxedo system. Equivalent COBOL library functions are also available; for details, see the *Oracle Tuxedo COBOL Function Reference*.

Context Attributes

When writing your code, keep in mind the following considerations about contexts:

- If an application-created server thread exits without changing context before the original dispatched thread exits, then `tpreturn(3c)` or `tpforward(3c)` fails. The execution of a thread exit does not automatically trigger a call to `tpsetctxt(3c)` to change the context to `TPNULLCONTEXT`.
- For all contexts in a process, the same buffer type switch must be used.
- As with any other type of data structure, a multithreaded application must properly make use of Oracle Tuxedo buffers, that is, buffers should not be used concurrently in two calls when one of the following may be true:
 - Both calls may use the buffer
 - Both calls may free the buffer
 - One call may use the buffer and one call may free the buffer
- If you call `tpinit(3c)` more than once, either to join multiple applications or to make multiple connections to a single application, keep in mind that on each `tpinit()` you must accommodate whatever security mechanisms have been established.

Setting Up Multicontexting at Initialization

When a client is ready to join an application, specify `tpiit(3c)` with the `TPMULTICONTEXTS` flag set, as shown in the following sample code.

Listing 10-1 Sample Code for a Client Joining a Multicontexted Application

```
#include <stdio.h>
#include <atmi.h>

TPINIT * tpinitbuf;

main()
{
    tpinitbuf = tpalloc(TPINIT, NULL, TPINITNEED(0));

    tpinitbuf->flags = TPMULTICONTEXTS;
    .
    .
    .
    if (tpinit (tpinitbuf) == -1) {
        ERROR_PROCESSING_CODE
    }
    .
    .
    .
}
```

A new application association is created and assigned to the Oracle Tuxedo domain specified in the `TUXCONFIG` or `WSENVFILE/WSNADDR` environment variable.

Note: In any one process, either all calls to `tpinit(3c)` must include the `TPMULTICONTEXTS` flag or else no call to `tpinit()` may include this flag. The only exception to this rule is that if all of a client's application associations are terminated by successful calls to `tpterm(3c)`, then the process is restored to a state in which the inclusion of the `TPMULTICONTEXTS` flag in the next call to `tpinit()` is optional.

Implementing Security for a Multicontexted ATMI Client

Each application association in the same process requires a separate security validation. The nature of that validation depends on the type of security mechanisms used in your application. In an Oracle Tuxedo application you might, for example, use a system-level password or an application password.

As the programmer of a multicontexted application, you are responsible for identifying the type of security used in your application and implementing it for each application association in a process.

Synchronizing Threads Before an ATMI Client Termination

When you are ready to disconnect a client from an application, invoke `tpterm(3c)`. Keep in mind, however, that in a multicontexted application `tpterm()` destroys the current context. All the threads operating on that context are affected. As the application programmer, you must carefully coordinate the use of multiple threads to make sure that `tpterm()` is not called unexpectedly.

It is important to avoid calling `tpterm(3c)` on a context while other threads are still working on that context. If such a call to `tpterm()` is made, the Oracle Tuxedo system places the other threads that had been associated with that context in a special invalid context state. When in the invalid context state, most ATMI functions are disallowed. A thread may exit from the invalid context state by calling `tpsetctxt(3c)` or `tpterm()`. Most well designed applications never have to deal with the invalid context state.

Note: The Oracle Tuxedo system does not support multithreading in COBOL applications.

Switching Contexts

The following is a summary of the coding steps that might be made by a client that calls services from two contexts.

1. Set the `TUXCONFIG` environment variable to the value required by `firstapp`.
2. Join the first application by calling `tpinit(3c)` with the `TPMULTICONTEXTS` flag set.
3. Obtain a handle to the current context by calling `tpgetctxt(3c)`.
4. Switch the value of the `TUXCONFIG` environment variable to the value required by the `secondapp` context, by calling `tuxputenv()`.
5. Join the second application by calling `tpinit(3c)` with the `TPMULTICONTEXTS` flag set.

6. Get a handle to the current context by calling `tpgetctxt(3c)`.
7. Beginning with the `firstapp` context, start toggling between contexts by calling `tpsetctxt(3c)`.
8. Call `firstapp` services.
9. Switch the client to the `secondapp` context (by calling `tpsetctxt(3c)`) and call `secondapp` services.
10. Switch the client to the `firstapp` context (by calling `tpsetctxt(3c)`) and call `firstapp` services.
11. Terminate the `firstapp` context by calling `tpterm(3c)`.
12. Switch the client to the `secondapp` context (by calling `tpsetctxt(3c)`) and call `secondapp` services.
13. Terminate the `secondapp` context by calling `tpterm(3c)`.

The following sample code provides an example of these steps.

Note: In order to simplify the sample, error checking code is not included.

Listing 10-2 Sample Code for Switching Contexts in a Client

```
#include <stdio.h>
#include "atmi.h"/* BEA Tuxedo header file */

#if defined(__STDC__) || defined(__cplusplus)
main(int argc, char *argv[])
#else
main(argc, argv)
int argc;
char *argv[];
#endif
{
    TPINIT * tpinitbuf;
    TPCONTEXT_T firstapp_contextID, secondapp_contextID;
    /* Assume that TUXCONFIG is initially set to /home/firstapp/TUXCONFIG*/
    /*
     * Attach to the BEA Tuxedo system in multicontext mode.
     */
    tpinitbuf=tpalloc(TPINIT, NULL, TPINITNEED(0));
    tpinitbuf->flags = TPMULTICONTEXTS;
```

```

if (tpinit((TPINIT *) tpinitbuf) == -1) {
(void) fprintf(stderr, "Tpinit failed\n");
exit(1);
}

/*
 * Obtain a handle to the current context.
 */
tpgetctxt(&firstapp_contextID, 0);

/*
 * Use tuxputenv to change the value of TUXCONFIG,
 * so we now tpinit to another application.
 */
tuxputenv("TUXCONFIG=/home/second_app/TUXCONFIG");

/*
 * tpinit to secondapp.
 */
if (tpinit((TPINIT *) tpinitbuf) == -1) {
(void) fprintf(stderr, "Tpinit failed\n");
exit(1);
}

/*
 * Get a handle to the context of secondapp.
 */
tpgetctxt(&secondapp_contextID, 0);

/*
 * Now you can alternate between the two contexts
 * using tpsetctxt and the handles you obtained from
 * * tpgetctxt. You begin with firstapp.
 */

tpsetctxt(firstapp_contextID, 0);

/*
 * You call services offered by firstapp and then switch
 * to secondapp.
 */

tpsetctxt(secondapp_contextID, 0);

/*
 * You call services offered by secondapp.
 * Then you switch back to firstapp.
 */

```

```

tpsetctxt(firstapp_contextID, 0);

/*
 * You call services offered by firstapp. When you have
 * finished, you terminate the context for firstapp.
 */

tpterm();

/*
 * Then you switch back to secondapp.
 */

tpsetctxt(secondapp_contextID, 0);
/*
 * You call services offered by secondapp. When you have
 * finished, you terminate the context for secondapp and
 * end your program.
 */

tpterm();

return(0);
}

```

Handling Unsolicited Messages

For each context in which you want to handle unsolicited messages, you must set up an unsolicited message handler or use the process handler default if you have set one up.

If `tpsetunsol(3c)` is called from a thread that is not associated with a context, a per-process default unsolicited message handler for all new `tpinit(3c)` contexts created is established. A specific context may change the unsolicited message handler for that context by calling `tpsetunsol()` again when the context is active. The per-process default unsolicited message handler may be changed by again calling `tpsetunsol()` in a thread not currently associated with a context.

Set up the handler in the same way you set one up for a single-threaded or single-contexted application. See `tpsetunsol(3c)` for details.

You can use `tpgetctxt(3c)` in an unsolicited message handler if you want to identify the context in which you are currently working.

Coding Rules for Transactions in a Multithreaded/Multicontexted ATMI Application

The following consequences of using transactions should be kept in mind while you are writing your application:

- You can have only one transaction in any one context.
- You can have a different transaction for each context.
- All the threads associated with a given context at a given time share the same transaction state (if any) of that context.
- You must synchronize your threads so all conversations and RPC calls are complete before you call `tpcommit(3c)`.
- You can call `tpcommit(3c)` from only one thread in any particular transaction.

Writing Code to Enable Multicontexting and Multithreading in an ATMI Server

This topic includes the following sections:

- [Coding Rules for a Multicontexted ATMI Server](#)
- [Initializing and Terminating ATMI Servers and Server Threads](#)
- [Programming an ATMI Server to Create Threads](#)
- [Sample Code for Creating an Application Thread in a Multicontexted ATMI Server](#)

Note: The instructions and sample code provided in this section refer to the C library functions provided by the Oracle Tuxedo system. (See the *Oracle Tuxedo C Function Reference* for details.) Equivalent COBOL routines are not available because multithreading (which is required to create a multicontexted server) is not supported for COBOL applications.

Context Attributes

When writing your code, keep in mind the following considerations about contexts:

- If an application-created server thread exits without changing context before the original dispatched thread exits, then `tpreturn(3c)` or `tpforward(3c)` fails. The execution of a thread exit does not automatically trigger a call to `tpsetctxt(3c)` to change the context to `TPNULLCONTEXT`.
- For all contexts in a process, the same buffer type switch must be used.
- As with any other type of data structure, a multithreaded application must properly make use of Oracle Tuxedo buffers, that is, buffers should not be used concurrently in two calls when one of the following may be true:
 - Both calls may use the buffer.
 - Both calls may free the buffer.
 - One call may use the buffer and one call may free the buffer.

Coding Rules for a Multicontexted ATMI Server

Keep in mind the following rules for coding multicontexted servers:

- The Oracle Tuxedo dispatcher on the server may dispatch the same service and/or different services multiple times, creating a different dispatch context for each service dispatched.

- A server is prohibited from calling `tpinit(3c)` or otherwise acting as a client. If a server process calls `tpinit()`, `tpinit()` returns -1 and sets `tperrno(5)` to `TPEPROTO`. An application-created server thread may not make ATMI calls before calling `tpsetctxt(3c)`.
- Only a server-dispatched thread may call `tpreturn(3c)` or `tpforward(3c)`.
- A server cannot execute a `tpreturn(3c)` or `tpforward(3c)` if any application-created thread is still associated with any application context. Therefore, before a server-dispatched thread calls `tpreturn()`, each application-created thread associated with that context must call `tpsetctxt(3c)` with the context set to either `TPNULLCONTEXT` or another valid context.

If this rule is violated, then `tpreturn(3c)` or `tpforward(3c)` writes a message to the user log, indicates `TPESVCERR` to the caller, and returns control to the main server dispatch loop. The threads that had been in the context where the invalid `tpreturn()` was done are placed in an invalid context.

- If there are outstanding ATMI calls, RPC calls, or conversations when `tpreturn(3c)` or `tpforward(3c)` is called, `tpreturn()` or `tpforward()` writes a message to the user log, indicates `TPESVCERR` to the caller, and returns control to the main server dispatch loop.
- A server-dispatched thread may not call `tpsetctxt(3c)`.
- Unlike single-contexted servers, it is permissible for a multicontexted server thread to call a service that is offered only by that same server process.

Initializing and Terminating ATMI Servers and Server Threads

To initialize and terminate your servers and server threads, you can use the default functions provided by the Oracle Tuxedo system or you can use your own.

Table 10-1 Default Functions for Initialization and Termination

To ...	Use the default function
Initialize a server	<code>tpsvrinit(3c)</code>
Initialize a server thread	<code>tpsvrthrinit(3c)</code>

Table 10-1 Default Functions for Initialization and Termination

To . . .	Use the default function
Terminate a server	<code>tpsvrdone(3c)</code>
Terminate a server thread	<code>tpsvrthrdone(3c)</code>

Programming an ATMI Server to Create Threads

You may create additional threads within an application server, although most applications using multicontexted servers use only the dispatched server threads created by the system. This section provides instructions for doing so.

Creating Threads

You may create additional threads within an application server by using OS threads functions. These new threads may operate independently of the Oracle Tuxedo system, or they may operate in the same context as one of the server-dispatched threads.

Associating Threads with a Context

Initially, application-created server threads are not associated with any server-dispatched context. If called before being initialized, however, most ATMI functions perform an implicit `tpinit(3c)`. Such calls introduce problems because servers are prohibited from calling `tpinit()`. (If a server process calls `tpinit()`, `tpinit()` returns -1 and sets `tperrno(5)` to `TPEPROTO`.)

Therefore, an application-created server thread must associate itself with an existing context before calling any ATMI functions. To associate an application-created server thread with an existing context, you must write code that implements the following procedure.

1. Server-dispatched-thread_A gets a handle to the current context by calling `tpgetctxt(3c)`.
2. Server-dispatched-thread_A passes the handle returned by `tpgetctxt(3c)` to Application_thread_B.
3. Application_thread_B associates itself with the current context by calling `tpsetctxt(3c)`, specifying the handle received from Server-dispatched-thread_A.
4. Application-created server threads cannot call `tpreturn(3c)` or `tpforward(3c)`. Before the originally dispatched thread calls `tpreturn()` or `tpforward()`, all application-created

server threads that have been in that context must switch to `TPNULLCONTEXT` or another valid context.

If this rule is not observed, then `tpforward(3c)` or `tpreturn(3c)` fails and indicates a service error to the caller.

Sample Code for Creating an Application Thread in a Multicontexted ATMI Server

For those applications with a need to create an application thread in a server, the following code sample shows a multicontexted server in which a service creates another thread to help perform its work. Operating system (OS) threads functions differ from one OS to another. In this sample POSIX and ATMI functions are used.

Notes: In order to simplify the sample, error checking code is not included. Also, an example of a multicontexted server using only threads dispatched by the Oracle Tuxedo system is not included because such a server is coded in exactly the same way as a single-contexted server, as long as thread-safe programming practices are used.

Listing 10-3 Code Sample for Creating a Thread in a Multicontexted Server

```
#include <pthread.h>
#include <atmi.h>

void *withdrawalthread(void *);

struct sdata {
    TPCONTEXT_T    ctxt;
    TPSVCINFO      *svcinfp;
};

void
TRANSFER(TPSVCINFO *svcinfp)
{
    struct sdata    transferdata;
    pthread_t       withdrawalthreadid;

    tpgetctxt(&transferdata.ctxt, 0);
    transferdata.svcinfo = svcinfp;
    pthread_create(&withdrawalthreadid, NULL, withdrawalthread, &transferdata);
    tpcall("DEPOSIT", ...);
    pthread_join(withdrawalthreadid, NULL);
    tpreturn(TPSUCCESS, ...);
}
```

```

}

void *
withdrawalthread(void *arg)
{
    tpsetctxt(arg->ctxt, 0);
    tpopen();
    tpcall("WITHDRAWAL", ...);
    tpclose();
    return(NULL);
}

```

The previous example accomplishes a funds transfer by invoking the `DEPOSIT` service in the originally dispatched thread, and `WITHDRAWAL` in an application-created thread. This example is based on the assumption that the resource manager being used allows a mixed model such that multiple threads of a server can be associated with a particular database connection without all threads of the server being associated with that instance. Most resource managers, however, do not support such a model.

A simpler way to code this example is to avoid the use of an application-created thread. To obtain the same concurrency provided by the two calls to `tpcall(3c)` in the example, substitute two calls to `tpacall(3c)` and two calls to `tpgetrply(3c)` in the server-dispatched thread.

Note: The Oracle Tuxedo system does not support multithreaded COBOL applications.

Coding Rules for a Multithreaded ATMI Client

Keep in mind the following rules for coding multithreaded clients:

- Once a conversation has been started, any thread in the same process can work on that conversation. Handles and call descriptors are portable within the same context in the same process, but not between contexts or processes. Handles and call descriptors can be used only in the application context in which they are originally assigned.
- Any thread operating in the same context within the same process can invoke `tpgetrply(3c)` to receive a response to an earlier call to `tpacall(3c)`, regardless of whether or not that thread originally called `tpacall()`.
- A transaction can be committed or aborted by only one thread, which may or may not be the same thread that started it.
- All RPC calls and conversations must be completed before an attempt is made to commit the transaction. If an application calls `tpcommit(3c)` while RPC calls or conversations are outstanding, `tpcommit()` aborts the transaction, returns `-1`, and sets `tperrno(5)` to `TPEABORT`.

- Functions such as `tpcall(3c)`, `tpacall(3c)`, `tpgetrply(3c)`, `tpconnect(3c)`, `tpsend(3c)`, `tprecv(3c)`, and `tpdiscon(3c)` should not be called in transaction mode unless you are sure that the transaction is not already committing or aborting.
- Two `tpbegin(3c)` calls cannot be made simultaneously for the same context.
- `tpbegin(3c)` cannot be issued for a context that is already in transaction mode.
- If you are using a client and you want to connect to more than one domain, you must manually change the value of `TUXCONFIG` or `WSNADDR` before calling `tpinit(3c)`. You must synchronize the setting of the environment variable and the `tpinit()` call if multiple threads may be performing such an action. All application associations in a client must obey the following rules:
 - All associations must be made to the same release of the Oracle Tuxedo system.
 - Either every application association in a particular client must be made as a native client, or every application association must be made as a Workstation client.
- To join an application, a multithreaded Workstation client must always call `tpinit(3c)` with the `TPMULTICONTEXTS` flag set, even if the client is running in single-context mode.

Initializing an ATMI Client to Multiple Contexts

To have a client join more than one context, issue a call to the `tpinit(3c)` function with the `TPMULTICONTEXTS` flag set in the `flags` element of the `TPINIT` data structure.

In any one process, either all calls to `tpinit(3c)` must include the `TPMULTICONTEXTS` flag or no call to `tpinit()` may include this flag. The only exception to this rule is that if all of a client's application associations are terminated by successful calls to `tpterm(3c)`, then the process is restored to a state in which the inclusion of the `TPMULTICONTEXTS` flag in the next call to `tpinit()` is optional.

When `tpinit(3c)` is invoked with the `TPMULTICONTEXTS` flag set, a new application association is created and is designated the current association. The Oracle Tuxedo domain to which the new association is made is determined by the value of the `TUXCONFIG` or `WSENVFILE/WSNADDR` environment variable.

When a client thread successfully executes `tpinit(3c)` without the `TPMULTICONTEXTS` flag, all threads in the client are placed in the single-context state (`TPSINGLECONTEXT`).

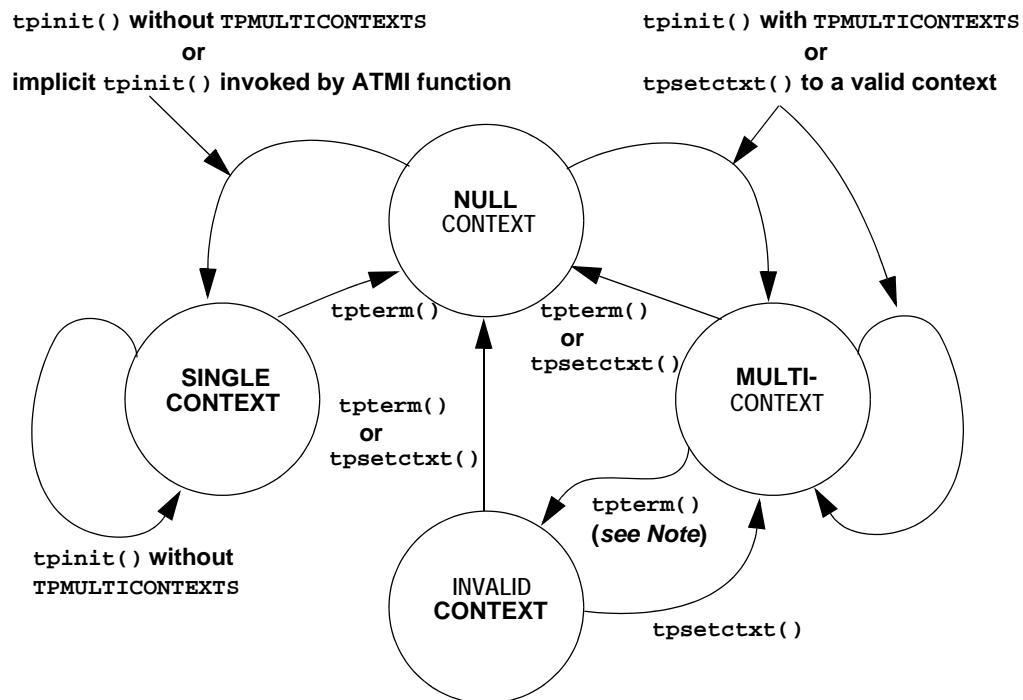

On failure, `tpinit(3c)` leaves the calling thread in its original context (that is, in the context state in which it was operating before the call to `tpinit()`).

Do not call `tpterm(3c)` from a given context if any of the threads in that context are still working. See the table labeled “[Multicontext State Transitions](#)” on [page 10-40](#) for a description of the context states that result from calling `tpterm()` under these and other circumstances.

Context State Changes for an ATMI Client Thread

In a multicontext application, calls to various functions result in context state changes for the calling thread and any other threads that are active in the same context as the calling process. [Figure 10-4](#) illustrates the context state changes that result from calls to `tpinit(3c)`, `tpsetctxt(3c)`, and `tpterm(3c)`. (The `tpgetctxt(3c)` function does not produce any context state changes.)

Figure 10-4 Multicontext State Transitions

Note: When `tpterm(3c)` is called by a thread running in the multicontext state (`TPMULTICONTEXTS`), the calling thread is placed in the null context state

(TPNULLCONTEXT). All other threads associated with the terminated context are switched to the invalid context state (TPINVALIDCONTEXT).

Table 10-2 lists all possible context state changes produced by calling `tpinit(3c)`, `tpsetctxt(3c)`, and `tpterm(3c)`.

Table 10-2 Context State Changes for a Client Thread

When this function is executed . . .	Then a thread in this context state results in . . .			
	Null Context	Single Context	Multicontext	Invalid Context
<code>tpinit(3c)</code> without TPMULTICONTEXTS	Single context	Single context	Error	Error
<code>tpinit(3c)</code> with TPMULTICONTEXTS	Multicontext	Error	Multicontext	Error
<code>tpsetctxt(3c)</code> to TPNULLCONTEXT	Null	Error	Null	Null
<code>tpsetctxt(3c)</code> to context 0	Error	Single context	Error	Error
<code>tpsetctxt(3c)</code> to context > 0	Multicontext	Error	Multicontext	Multicontext
Implicit <code>tpinit(3c)</code>	Single context	N/A	N/A	Error
<code>tpterm(3c)</code> in this thread	Null	Null	Null	Null
<code>tpterm(3c)</code> in a different thread of this context	N/A	Null	Invalid	N/A

Getting Replies in a Multithreaded Environment

`tpgetrply(3c)` receives responses only to requests made via `tpacall(3c)`. Requests made with `tpcall(3c)` are separate and cannot be retrieved with `tpgetrply()` regardless of the multithreading or multicontexting level.

`tpgetrply(3c)` operates in only one context, which is the context in which it is called. Therefore, when you call `tpgetrply()` with the `TPGETANY` flag, only handles generated in the same context are considered. Similarly, a handle generated in one context may not be used in another context, but the handle may be used in any thread operating within the same context. When `tpgetrply(3c)` is called in a multithreaded environment, the following restrictions apply:

- If a thread calls `tpgetrply(3c)` for a specific handle while another thread in the same context is already waiting in `tpgetrply()` for the same handle, `tpgetrply()` returns `-1` and sets `tperrno` to `TPEPROTO`.
- If a thread calls `tpgetrply(3c)` for a specific handle while another thread in the same context is already waiting in `tpgetrply()` with the `TPGETANY` flag, the call returns `-1` and sets `tperrno(5)` to `TPEPROTO`.

The same behavior occurs if a thread calls `tpgetrply(3c)` with the `TPGETANY` flag while another thread in the same context is already waiting in `tpgetrply()` for a specific handle. These restrictions protect a thread that is waiting on a specific handle from having its reply taken by a thread waiting on any handle.

- At any given time, only one thread in a particular context can wait in `tpgetrply(3c)` with the `TPGETANY` flag set. If a second thread in the same context invokes `tpgetrply()` with the `TPGETANY` flag while a similar call is outstanding, this second call returns `-1` and sets `tperrno(5)` to `TPEPROTO`.

Using Environment Variables in a Multithreaded and/or Multicontexted Environment

When an Oracle Tuxedo application is run in an environment that is multicontexted and/or multithreaded, the following considerations apply to the use of environment variables:

- A process initially inherits its environment from the operating system environment. On platforms that support environment variables, such variables make up a per-process entity. Therefore, applications that depend on per-context environment settings should use the `tuxgetenv(3c)` function instead of an OS function.

Note: The environment is initially empty for those operating systems that do not recognize an operating system environment.

- Many environment variables are read by the Oracle Tuxedo system only once per process or once per context and then cached within the Oracle Tuxedo system. Changes to such variables once cached in the process have no effect.

Caching is done on a . . .	For environment variables such as . . .
Per-context basis	TUXCONFIG
	FLDGTBLS and FLDGTBLS32
	FLDTBLDIR and FLDTBLDIR32
	ULOGPFX
	VIEWDIR and VIEWDIR32
	VIEWFILES and VIEWFILES32
	WSNADDR
	WSDEVICE
	WSENV
Per-process basis	TMTRACE
	TUXDIR
	ULOGDEBUG

- The `tuxputenv(3c)` function affects the environment for the entire process.
- When you call the `tuxreadenv(3c)` function, it reads a file containing environment variables and adds them to the environment for the entire process.
- The `tuxgetenv(3c)` function returns the current value of the requested environment variable in the current context. Initially, all contexts have the same environment, but the use of environment files specific to a particular context can cause different contexts to have different environment settings.
- If a client intends to initialize to more than one domain, the client must change the value of the `TUXCONFIG`, `WSNADDR`, or `WSENVFILE` environment variable to the proper value before each call to `tpinit(3c)`. If such an application is multithreaded, a mutex or other application-defined concurrency control will probably be needed to ensure that:
 - The appropriate environment variable is reset.
 - The call to `tpinit(3c)` is made without the environment variable being reset by any other thread.

- When a client initializes to the system, the `WSENVFILE` and/or machine environment file is read and affects the environment in that context only. The previous environment for the process as a whole remains for that context to the extent that it is not overridden within the environment file(s).

Using Per-context Functions and Data Structures in a Multithreaded ATMI Client

The following ATMI functions affect only the application contexts in which they are called:

- `tpabort(3c)`
- `tpacall(3c)`
- `tpadmcall(3c)`
- `tpbegin(3c)`
- `tpbroadcast(3c)`
- `tpcall(3c)`
- `tpcancel(3c)`
- `tpchkauth(3c)`
- `tpchkunsol(3c)`
- `tpclose(3c)`
- `tpcommit(3c)`
- `tpconnect(3c)`
- `tpdequeue(3c)`
- `tpdiscon(3c)`
- `tpenqueue(3c)`
- `tpforward(3c)`
- `tpgetlev(3c)`
- `tpgetrply(3c)`
- `tpinit(3c)`
- `tpnotify(3c)`
- `tpopen(3c)`
- `tppost(3c)`

- `tprecv(3c)`
- `tpresume(3c)`
- `tpreturn(3c)`
- `tpscmt(3c)`
- `tpsend(3c)`
- `tpservice(3c)`
- `tpsetunsol(3c)`
- `tpsubscribe(3c)`
- `tpsuspend(3c)`
- `tpterm(3c)`
- `tpunsubscribe(3c)`
- `tx_begin(3c)`
- `tx_close(3c)`
- `tx_commit(3c)`
- `tx_info(3c)`
- `tx_open(3c)`
- `tx_rollback(3c)`
- `tx_set_commit_return(3c)`
- `tx_set_transaction_control(3c)`
- `tx_set_transaction_timeout(3c)`
- `userlog(3c)`

Note: For `tpbroadcast(3c)`, the broadcast message is identified as having come from a particular application association. For `tpnotify(3c)`, the notification is identified as having come from a particular application association. See “Using Per-process Functions and Data Structures in a Multithreaded Client” for notes about `tpinit(3c)`.

If `tpsetunsol(3c)` is called from a thread that is not associated with a context, a per-process default unsolicited message handler for all new `tpinit(3c)` contexts created is established. A specific context may change the unsolicited message handler for that context by calling `tpsetunsol()` again when the context is active. The per-process default unsolicited message handler may be changed by again calling `tpsetunsol()` in a thread not currently associated with a context.

- The `CLIENTID`, client name, username, transaction ID, and the contents of the `TPSVCINFO` data structure may differ from context to context within the same process.
- Asynchronous call handles and connection descriptors are valid in the contexts in which they are created. The unsolicited notification type is specific per-context. Although signal-based notification may not be used with multiple contexts, each context may choose one of three options:
 - Ignoring unsolicited messages
 - Using dip-in notification
 - Using dedicated thread notification

Using Per-process Functions and Data Structures in a Multithreaded ATMI Client

The following Oracle Tuxedo functions affect the entire process in which they are called:

- `tpadvertise(3c)`
- `tpalloc(3c)`
- `tpconvert(3c)`—the requested structure is converted, although it is probably relevant to only a subset of the process.
- `tpfree(3c)`
- `tpinit(3c)`—to the extent that the per-process `TPMULTICONTEXTS` mode or single-context mode is established. See also “Using Per-context Functions and Data Structures in a Multithreaded ATMI Client” on page 10-44.
- `tprealloc(3c)`
- `tpsvrdone(3c)`
- `tpsvrinit(3c)`
- `tpypes(3c)`
- `tpunadvertise(3c)`
- `tuxgetenv(3c)`—if the OS environment is per-process.
- `tuxputenv(3c)`—if the OS environment is per-process.
- `tuxreadenv(3c)`—if the OS environment is per-process.
- `Usignal(3c)`

The determination of single-context mode, multicontext mode, or uninitialized mode affects an entire process. The buffer type switch, the view cache, and environment variable values are also per-process functions.

Using Per-thread Functions and Data Structures in a Multithreaded ATMI Client

Only the calling thread is affected by the following:

- CATCH
- `tperrordetail(3c)`
- `tpgetctxt(3c)`
- `tpgprio(3c)`
- `tpsetctxt(3c)`
- `tpsprio(3c)`
- `tpstrerror(3c)`
- `tpstrerrordetail(3c)`
- `TRY(3c)`
- `Unix_err(3c)`

The `Error`, `Error32(5)`, `tperrno(5)`, `tpurcode(5)`, and `Unix_err` variables are specific to each thread.

The identity of the current context is specific to each thread.

Sample Code for a Multithreaded ATMI Client

The following example shows a multithreaded client using ATMI calls. Threads functions differ from one operating system to another. In this example, POSIX functions are used.

Note: In order to simplify this example, error checking code has not been included.

Listing 10-4 Sample Code for a Multithreaded Client

```
#include <stdio.h>
#include <pthread.h>
#include <atmi.h>
```

```

TPINIT *    tpinitbuf;
int      timeout=60;
pthread_t withdrawalthreadid, stockthreadid;
TPCONTEXT_T  ctxt;
void * stackthread(void *);
void * withdrawalthread(void *);

main()
{
    tpinitbuf = tpalloc(TPINIT, NULL, TPINITNEED(0));
    /*
     * This code will perform a transfer, using separate threads for the
     * withdrawal and deposit.  It will also get the current
     * price of BEA stock from a separate application, and calculate how
     * many shares the transferred amount can buy.
     */

    tpinitbuf->flags = TPMULTICONTEXTS;

    /* Fill in the rest of tpinitbuf. */
    tpinit(tpinitbuf);

    tpgetctxt(&ctxt, 0);
    tpbegin(timeout, 0);
    pthread_create(&withdrawalthreadid, NULL, withdrawalthread, NULL);
    tpcall("DEPOSIT", ...);

    /* Wait for the withdrawal thread to complete. */
    pthread_join(withdrawalthreadid, NULL);

    tpcommit(0);
    tpterm();

    /* Wait for the stock thread to complete. */
    pthread_join(stockthreadid, NULL);

    /* Print the results. */
    printf("$%9.2f has been transferred \
from your savings account to your checking account.\n", ...);

    printf("At the current BEA stock price of $%8.3f, \
you could purchase %d shares.\n", ...);

    exit(0);
}

void *

```

```

stockthread(void *arg)
{
    /* The other threads have now called tpinit(), so resetting TUXCONFIG can
     * no longer adversely affect them.
     */

    tuxputenv("TUXCONFIG=/home/users/xyz/stockconf");
    tpinitbuf->flags = TPMULTICONTEXTS;
    /* Fill in the rest of tpinitbuf. */
    tpinit(tpinitbuf);
    tpcall("GETSTOCKPRICE", ...);
    /* Save the stock price in a variable that can also be accessed in main(). */
    tpterm();
    return(NULL);
}

void *
withdrawalthread(void *arg)
{
    /* Create a separate thread to get stock prices from a different
     * application.
     */

    pthread_create(&stockthreadid, NULL, stockthread, NULL);
    tpsetctxt(ctxt, 0);
    tpcall("WITHDRAWAL", ...);
    return(NULL);
}

```

Writing a Multithreaded ATMI Server

Multithreaded servers are almost always multicontexted, as well. For information about writing a multithreaded server, see [“Writing Code to Enable Multicontexting and Multithreading in an ATMI Server” on page 10-33](#).

Compiling Code for a Multithreaded/Multicontexted ATMI Application

The programs provided by the Oracle Tuxedo system for compiling or building executables, such as `buildserver(1)` and `buildclient(1)`, automatically include any required compiler flags. If you use these tools, then you do not need to set any flags at compile time.

If, however, you compile your `.c` files into `.o` files before doing a final compilation, you may need to set platform-specific compiler flags. Such flags must be set consistently for all code linked into a single process.

If you are creating a multithreaded server, you must run the `buildserver(1)` command with the `-t` option. This option is mandatory for multithreaded servers; if you do not specify it at build time and later try to boot the new server with a configuration file in which the value of `MAXDISPATCHTHREADS` is greater than 1, a warning message is recorded in the user log and the server reverts to single-threaded operation.

To identify any operating system-specific compiler parameters that are required when you compile `.c` files into `.o` files in a multithreaded environment, run `buildclient(1)` or `buildserver(1)` with the `-v` option set on a test file.

Testing a Multithreaded/Multicontexted ATMI Application

This topic includes the following sections:

- [Testing Recommendations for a Multithreaded/Multicontexted ATMI Application](#)

- [Troubleshooting a Multithreaded/Multicontexted ATMI Application](#)
- [Error Handling for a Multithreaded/Multicontexted ATMI Application](#)

Testing Recommendations for a Multithreaded/Multicontexted ATMI Application

We recommend following these recommendations during testing of your multithreaded and/or multicontexted code:

- Use a multiprocessor.
- Use a multithreaded debugger (if your operating system vendor offers one).
- Run stress tests to introduce a variety of timing conditions.

Troubleshooting a Multithreaded/Multicontexted ATMI Application

When you need to investigate possible causes of errors, we recommend that you start by checking whether and how the `TPMULTICONTEXTS` flag has been set. Errors are frequently introduced by failures to set this flag or to set it properly.

Improper Use of the `TPMULTICONTEXTS` Flag to `tpinit()`

If a process includes the `TPMULTICONTEXTS` flag in a state for which this flag is not allowed (or omits `TPMULTICONTEXTS` in a state that requires it), then `tpinit(3c)` returns `-1` and sets `tperrno` to `TPEPROTO`.

Calls to `tpinit()` Without `TPMULTICONTEXTS`

When `tpinit(3c)` is invoked without `TPMULTICONTEXTS`, it behaves as it does when called in a single-contexted application. When `tpinit()` has been invoked once, subsequent `tpinit()` calls without the `TPMULTICONTEXTS` flag succeed without further action. This is true even if the value of the `TUXCONFIG` or `WSNADDR` environment variable in the application has been changed. Calling `tpinit()` without the `TPMULTICONTEXTS` flag set is not allowed in multicontext mode.

If a client has not joined an application and `tpinit(3c)` is called implicitly (as a result of a call to another function that calls `tpinit()`), then the Oracle Tuxedo system interprets the action as a call to `tpinit()` without the `TPMULTICONTEXTS` flag for purposes of determining which flags may be used in subsequent calls to `tpinit()`.

For most ATMI functions, if a function is invoked by a thread that is not associated with a context in a process already operating in multicontext mode, the ATMI function fails with `tperrno(5)=TPEPROTO`.

Insufficient Thread Stack Size

On certain operating systems, the operating system default thread stack size is insufficient for use with the Oracle Tuxedo system. Compaq Tru64 UNIX and UnixWare are two operating systems for which this is known to be the case. If the default thread stack size parameter is used, applications on these platforms dump core when a function with substantial stack usage requirements is called by any thread other than the main thread. Often the core file that is created does not give any obvious clues to the fact that an insufficient stack size is the cause of the problem.

When the Oracle Tuxedo system is creating threads on its own, such as server-dispatched threads or a client unsolicited message thread, it can adjust the default stack size parameter on these platforms to a sufficient value. However, when an application is creating threads on its own, the application must specify a sufficient stack size. At a minimum, a value of 128K should be used for any thread that will access the Oracle Tuxedo system.

On Compaq Tru64 UNIX and other systems on which POSIX threads are used, a thread stack size is specified by invoking `pthread_attr_setstacksize()` before calling `pthread_create()`. On UnixWare, the thread stack size is specified as an argument to `thr_create()`. Consult your operating system documentation for further information on this subject.

Error Handling for a Multithreaded/Multicontexted ATMI Application

Errors are reported in the user log. For each error, whether in single-context mode or multicontext mode, the following information is recorded:

process_ID.thread_ID.context_ID

Managing Errors

This topic includes the following sections:

- [System Errors](#)
- [Application Errors](#)
- [Handling Errors](#)
- [Transaction Considerations](#)
- [Central Event Log](#)

System Errors

The Oracle Tuxedo system uses `TP-STATUS` IN `TPSTATUS-REC` to supply information to a process when a routine fails. All ATMI calls set `TP-STATUS` to a value that describes the nature of the error. When a call does not return to its caller, as in the case of `TPRETURN` or `TPFORWAR`, which are used to terminate a service routine, the only way the system can communicate success or failure is through `TP-STATUS` in the requester.

`APPL-RETURN-CODE` is used to communicate user-defined conditions only. The system sets the value of `APPL-RETURN-CODE` to the value of `APPL-CODE` IN `TPSVCRET-REC` during `TPRETURN`. The system sets `APPL-RETURN-CODE`, regardless of the value of `APPL-RETURN-CODE` IN `TPSTATUS-REC` during `TPRETURN`, unless an error is encountered by `TPRETURN` or a transaction timeout occurs.

The codes returned in `TP-STATUS` represent categories of errors, which are listed in [Table 11-1](#).

Table 11-1 TP-STATUS Error Categories

Error Category	TP-STATUS Values
Abort	TPEABORT ²
Oracle Tuxedo system ¹	TPESYSTEM
Communication handle	TPELIMIT and TPEBADDESC
Conversational	TPEVENT
Duplicate operation	TPEMATCH
General communication	TPEVCFAIL, TPEVCERR, TPEBLOCK, and TPGOTSIG
Heuristic decision	TPEHAZARD ² and TPEHEURISTIC ²
Invalid argument ¹	TPEINVAL
MIB	TPEMIB
No entry	TPENOENT
Operating system ¹	TPEOS
Permission	TPEPERM
Protocol ¹	TPEPROTO
Queueing	TPEDIAGNOSTIC
Release compatibility	TPERELEASE
Resource manager	TPERMERR
Timeout	TPETIME
Transaction	TPETRAN ²
Typed record mismatch	TPEITYPE and TPEOTYPE

1. Applicable to all ATMI calls for which failure is reported by the value returned in TP-STATUS.

2. Refer to [“Fatal Transaction Errors” on page 11-14](#) for more information on this error category.

As footnote 1 shows, four categories of errors are reported by TP-STATUS and are applicable to all ATMI calls. The remaining categories are used only for specific ATMI calls. The following sections describe some error categories in detail.

Abort Errors

For information on the errors that lead to abort, refer to [“Fatal Transaction Errors” on page 11-14](#).

Oracle Tuxedo System Errors

Oracle Tuxedo system errors indicate problems at the *system level*, rather than at the application level. When Oracle Tuxedo system errors occur, the system writes messages explaining the exact nature of the errors to the central event log, and returns TPESYSTEM in TP-STATUS. For more information, refer to the [“Central Event Log” on page 11-21](#). Because these errors occur in the system, rather than in the application, you may need to consult the system administrator to correct them.

Communication Handle Errors

Communication handle errors occur as a result of exceeding the maximum limit of communication handles or referencing an invalid value. Asynchronous and conversational calls return TPELIMIT when the maximum number of outstanding communication handles has been exceeded. TPEBADDESC is returned when an invalid communication handle value is specified for an operation.

Communication handle errors occur only during asynchronous calls or conversational calls. (Call descriptors are not used for synchronous calls.) Asynchronous calls depend on communication handles to associate replies with the corresponding requests. Conversational send and receive routines depend on communication handles to identify the connection; the call that initiates the connection depends on the availability of a communication handle.

Communication handle errors can be done by checking for specific errors at the application level.

Limit Errors

The system allows up to 50 outstanding communication handles (replies) per context (or Oracle Tuxedo application association). This limit is enforced by the system; it cannot be redefined by your application.

The limit for communication handles for simultaneous conversational connections is more flexible than the limit for replies. The application administrator defines the limit in the configuration file. When the application is not running, the administrator can modify the `MAXCONV` parameter in the `RESOURCES` section of the configuration file. When the application is running, the administrator can modify the `MACHINES` section dynamically. Refer to [tmconfig](#), [wtmconfig\(1\)](#) in the *Oracle Tuxedo Command Reference* for more information.

Invalid Descriptor Errors

A communication handle can become invalid and, if referenced, cause an error to be returned to `TP-STATUS` in either of two situations:

- A communication handle is used to retrieve a message, which may be a failed message (`TPEBADDESC`).
- An attempt is made to reuse a stale communication handle (`TPEBADDESC`).

A communication handle might become stale, for example, in the following circumstances:

- When the application calls `TPABORT` or `TPCOMMIT` and transaction replies (sent without `TPNOTRAN`) remain to be retrieved.
- A transaction times out. When the timeout is reported by a call to `TPGETRPLY`, no message is retrieved using the specified handle and the handle becomes stale.

Conversational Errors

When an unknown handle is specified for conversational services, the `TPSEND`, `TPRECV`, and `TPDISCON` routines return `TPEBADDESC`.

When `TPSEND` and `TPRECV` fail with a `TPEEVENT` error after a conversational connection is established, an event has occurred. Data may or may not be sent by `TPSEND`, depending on the event. The system returns `TPEEVENT` in the `TPEVENT` member of `TPSTATUS-REC` and the course of action is dictated by the particular event.

For a complete description of conversational events, refer to “[Understanding Conversational Communication Events](#)” in *Programming Oracle Tuxedo ATMI Applications Using C*.

Duplicate Object Error

The `TPEMATCH` error code is returned in `TP-STATUS` when an attempt is made to perform an operation that results in a duplicate object. The following table lists the routines that may return the `TPEMATCH` error code and the associated cause.

Routine	Cause
<code>TPADVERTISE</code>	The <i>svcname</i> specified is already advertised for the server but with a function other than <i>func</i> . Although the function fails, <i>svcname</i> remains advertised with its current function (that is, <i>func</i> does not replace the current function name).
<code>TPRESUME</code>	The <i>tranid</i> points to a transaction identifier that another process has already resumed. In this case, the caller's state with respect to the transaction is not changed.
<code>TPSUBSCRIBE</code>	The specified subscription information has already been listed with the EventBroker.

For more information on these routines, refer to the *Oracle Tuxedo ATMI COBOL Function Reference*.

General Communication Call Errors

General communication call errors can occur during any communication calls, regardless of whether those calls are synchronous or asynchronous. Any of the following errors may be returned in `TP-STATUS`: `TPESVCFAIL`, `TPESVCERR`, `TPEBLOCK`, or `TPGOTSIG`.

TPESVCFAIL and TPESVCERR Errors

If the reply portion of a communication fails as a result of a call to `TPCALL` or `TPGETRPLY`, the system returns `TPESVCERR` or `TPSEVCFAIL` to `TP-STATUS`. The system determines the error by the arguments that are passed to `TPRETURN` and the processing that is performed by this call.

If `TPRETURN` encounters an error in processing or handling arguments, the system returns an error to the original requester and sets `TP-STATUS` to `TPESVCERR`. The receiver determines that an error has occurred by checking the value of `TP-STATUS`. The system does not send the data from the `TPRETURN` call, and if the failure occurred on `TPGETRPLY`, it renders the call handle invalid.

If `TPRETURN` does not encounter the `TPESVCERR` error, then the value returned in `TP-RETURN-VAL` determines the success or failure of the call. If the application specifies `TPFAIL` in the `TP-RETURN-VAL`, the system returns `TPESVCFail` in `TP-STATUS` and sends the data message to the caller. If `TP-RETURN-VAL` is set to `TPSUCCESS`, the system returns successfully to the caller, `TP-STATUS` is not set, and the caller receives the data.

TPEBLOCK and TPGOTSIG Errors

The `TPEBLOCK` and `TPGOTSIG` error codes may be returned at the request or the reply end of a message and, as a result, can be returned for all communication calls.

The system returns `TPEBLOCK` when a blocking condition exists and the process sending a request (synchronously or asynchronously) indicates, by setting `TPNOBLOCK` that it does not want to wait on a blocking condition. A blocking condition can exist when a request is being sent if, for example, all the system queues are full.

When `TPCALL` indicates a no blocking condition, only the sending part of the communication is affected. If a call successfully sends a request, the system does not return `TPEBLOCK`, regardless of any blocking situation that may exist while the call waits for the reply.

The system returns `TPEBLOCK` for `TPGETRPLY` when a call is made `TPNOBLOCK` and a blocking condition is encountered while `TPGETRPLY` is awaiting the reply. This may occur, for example, if a message is not currently available.

The `TPGOTSIG` error indicates an interruption of a system call by a signal; this situation is not actually an error condition. If `TPSIGRSTRT` is set, the calls do not fail and the system does not return the `TPGOTSIG` error code in `TP-STATUS`.

Invalid Argument Errors

Invalid argument errors indicate that an invalid argument was passed to a routine. Any ATMI call that takes arguments can fail if you pass it arguments that are invalid. In the case of a call that returns to the caller, the call fails and causes `TP-STATUS` to be set to `TPEINVAL`. In the case of `TPRETURN` or `TPFORWAR`, the system sets `TP-STATUS` to `TPESVCERR` for either the `TPCALL` or `TPGETRPLY` call that initiated the request and is waiting for results to be returned.

You can correct an invalid argument error at the *application level* by ensuring that you pass only valid arguments to routines.

No Entry Errors

No entry errors result from a lack of entries in the system tables or the data structure used to identify record types. The meaning of the no entry type error, `TPENOENT`, depends on the call that is returning it. [Table 11-2](#) lists the calls that return this error and describes various causes of error.

Table 11-2 No Entry Errors

Call	Cause
TPINITIALIZE	The calling process cannot join the application because there is no space left in the bulletin board to make an entry for it. Check with the system administrator.
TPCALL TPACALL	The calling process references a service called <code>SERVICE-NAME</code> IN <code>TPSVCDEF-REC</code> that is not known to the system since there is no entry for it in the bulletin board. On an application level, ensure that you have referenced the service correctly; otherwise, check with the system administrator.
TPCONNECT	The system cannot connect to the specified name because the service named does not exist or it is not a conversational service.
TPGPRIOR	The calling process seeks a request priority when no request has been made. This is an application-level error.
TPUNADVERTISE	The system cannot unadvertise <code>SERVICE-NAME</code> IN <code>TPSVCDEF-REC</code> because the name is not currently advertised by the calling process.

Operating System Errors

Operating system errors indicate that an operating system call has failed. The system returns `TPEOS` in `TP-STATUS`. On UNIX systems, the system returns a numeric value identifying the failed system call in the global variable `Uunixerr`. To resolve operating system errors, you may need to consult your system administrator.

Permission Errors

If a calling process does not have the correct permissions to join the application, the `TPINITIALIZE` call fails, returning `TPEPERM` in `TP-STATUS`. Permissions are set in the configuration file, outside of the application. If you encounter this error, check with the application administrator to make sure the necessary permissions are set in the configuration file.

Protocol Errors

Protocol errors occur when an ATMI call is invoked, either in the wrong order or using an incorrect process. For example, a client may try to begin communicating with a server before joining the application. Or `TPCOMMIT` may be called by a transaction participant instead of the initiator.

You can correct a protocol error at the *application level* by enforcing the rules of order and proper usage of ATMI calls.

To determine the cause of a protocol error, answer the following questions:

- Is the call being made in the correct order?
- Is the call being made by the correct process?

Protocol errors return the `TPEPROTO` value in `TP-STATUS`.

Refer to “Introduction to the COBOL Application-Transaction Monitor Interface” in the *Oracle Tuxedo ATMI COBOL Function Reference* for more information.

Queuing Error

The `TPENQUEUE(3cbl)` or `TPDEQUEUE(3cbl)` routine returns `TPDIAGNOSTIC` in `TP-STATUS` if the enqueueing or dequeueing on a specified queue fails. The reason for failure can be determined by the diagnostic returned via the `ctl` record. For a list of valid `ctl` flags, refer to `TPENQUEUE(3cbl)` or `TPDEQUEUE(3cbl)` in the *Oracle Tuxedo ATMI COBOL Function Reference*.

Release Compatibility Error

The Oracle Tuxedo system returns `TPERELEASE` in `TP-STATUS` if a compatibility issue exists between multiple releases of an Oracle Tuxedo system participating in an application domain.

For example, the `TPERELEASE` error may be returned if the `TPACK` flag is set when issuing the `TPNOTIFY(3cbl)` routine (indicating that the caller blocks until an acknowledgment message is received from the target client), but the target client is using an earlier release of the Oracle Tuxedo system that does not support the `TPACK` acknowledgement protocol.

Resource Manager Errors

Resource manager errors can occur with calls to `TPOPEN(3cbl)` and `TPCLOSE(3cbl)`, in which case the system returns the value of `TPERMERR` in `TP-STATUS`. This error code is returned for `TPOPEN` when the resource manager fails to open correctly. Similarly, this error code is returned for `TPCLOSE` when the resource manager fails to close correctly. To maintain portability, the Oracle Tuxedo system does not return a more detailed explanation of this type of failure. To determine the exact nature of a resource manager error, you must interrogate the resource manager.

Timeout Errors

The Oracle Tuxedo system supports timeout errors to establish a limit on the amount of time that the application waits for a service request or transaction. The Oracle Tuxedo system supports two types of configurable timeout mechanisms: blocking and transaction.

A *blocking timeout* specifies the maximum amount of time that an application waits for a reply to a service request. The application administrator defines the blocking timeout for the system in the configuration file.

A *transaction timeout* defines the duration of a transaction, which may involve several service requests. To define the transaction timeout for an application, pass the `T-OUT` argument to `TPBEGIN`.

The system may return timeout errors on communication calls for either blocking or transaction timeouts, and on `TPCOMMIT` for transaction timeouts only. In each case, if a process is in transaction mode and the system returns `TPETIME` on a failed call, a transaction timeout has occurred.

By default, if a process is not in transaction mode, the system performs blocking timeouts.

If a process is not in transaction mode and a blocking timeout occurs on an asynchronous call, the communication call that blocked fails, but the call descriptor is still valid and may be used on a reissued call. Other communication is not affected.

When a transaction timeout occurs, the communication handle to an asynchronous transaction reply (specified without `TPNOTRAN`) becomes stale and may no longer be referenced.

`TPETIME` indicates a blocking timeout on a communication call if the call was not made in transaction mode or if `TPNOBLOCK` was not set.

Note: If you set `TPNOBLOCK`, a blocking timeout cannot occur because the call returns immediately if a blocking condition exists.

For additional information on handling timeout errors, refer to [“Transaction Considerations” on page 11-12](#).

Transaction Errors

For information on transactions and the non-fatal and fatal errors that can occur, refer to [“Transaction Considerations” on page 11-12](#).

Typed Record Errors

Typed record errors are returned when requests or replies to processes are sent in records of an unknown type. The `TPCALL` and `TPACALL` calls return `TPEITYPE` when a request data record is sent to a service that does not recognize the type of the record.

Processes recognize record types that are identified in both the configuration file and the Oracle Tuxedo system libraries that are linked into the process. These libraries define and initialize a data structure that identifies the typed records that the process recognizes. You can tailor the library to each process, or an application can supply its own copy of a file that defines the record types. An application can set up the record type data structure (referred to as a record type switch) on a process-specific basis. For more information, see [tuxtypes\(5\)](#) and [typesw\(5\)](#) in the *File Formats, Data Descriptions, MIBs, and System Processes Reference*.

The `TPCALL` and `TPGETRPLY` calls return `TPEOTYPE` when a reply message is sent in a record that is not recognized or not allowed by the caller. In the latter case, the record type is included in the type switch, but the type returned does not match the record that was allocated to receive the reply and a change in record type is not allowed by the caller. The caller indicates this preference by setting `TPNOCHANGE`. In this case, strong type checking is enforced; the system returns `TPEOTYPE` when it is violated. By default, weak type checking is used. In this case, a record type other than the type originally allocated may be returned, as long as that type is recognized by the caller. The rules for sending replies are that the reply record must be recognized by the caller and, if strong type checking has been indicated, you must observe it.

Application Errors

Within an application, you can pass information about user-defined errors to calling programs using the *r*code argument of TPRETURN. Also, the system sets the value of APPL-RETURN-CODE to the value of APPL-CODE IN TPSVCRET-REC during TPRETURN. For more information about [TPRETURN\(3cb1\)](#), refer to the *Oracle Tuxedo ATMI COBOL Function Reference*.

Handling Errors

Your application logic should test for error conditions for the calls that have return values, and take appropriate action when an error occurs.

The following example shows a typical method of handling errors. The term ATMICALL(3) is used in this example to represent a generic ATMI call.

Listing 11-1 Handling Errors

```
. . .
CALL "TPINITIALIZE" USING TPINFDEF-REC
                        USR-DATA-REC
                        TPSTATUS-REC.

IF NOT TPOK
    error message, EXIT PROGRAM
CALL "TPBEGIN" USING TPTRXDEF-REC
                        TPSTATUS-REC.

IF NOT TPOK
    error message, EXIT PROGRAM

    Make atmi calls
    Check return values

IF TPEINVAL
    DISPLAY "Invalid arguments were given."
IF TPEPROTO
    DISPLAY "A call was made in an improper context."
. . .

    Include all error cases described in the ATMICALL(3)
    reference page. Other return codes are not possible,
```

```
so there is no need to test them.  
. . .  
continue
```

The values of `TP-STATUS` provide details about the nature of each problem and suggest the level at which it can be corrected. If your application defines a list of error conditions specific to your processing, the same can be said for the values of `APPL-RETURN-CODE` IN `TPSTATUS-REC`.

Transaction Considerations

The following sections describe how various programming features work when used in transaction mode. The first section provides rules of basic communication etiquette that should be observed in code written for transaction mode.

Communication Etiquette

When writing code to be run in transaction mode, you must observe the following rules of basic communication etiquette:

- Processes that are participants in the same transaction must require replies for all requests. To include a request that requires no reply, set `TPACALL` to `TPNOTRAN` or `TPNOREPLY`.
- A service must retrieve all asynchronous transaction replies before calling `TPRETURN` or `TPFORWAR`. This rule must be observed regardless of whether the code is running in transaction mode.
- The initiator must retrieve all asynchronous transaction replies (made without `TPNOTRAN`) before calling `TPCOMMIT`.
- Replies must be retrieved for asynchronous calls that expect replies from non-participants of the transaction, that is, replies to requests made with `TPACALL` in which the transaction, but not the reply, is suppressed.
- If a transaction has not timed out but is marked “abort-only,” any further communication should be performed with `TPNOTRAN` set so that the results of the communication are preserved after the transaction is rolled back.
- If a transaction has timed out:

- The handle for the timed-out call becomes stale and any further reference to it returns `TPEBADDESC`.
- Further calls to `TPGETRPLY` or `TPRECV` for any outstanding handles return a global state of transaction timeout; the system sets `TP-STATUS` to `TPETIME`.
- Asynchronous calls can be made with `TPACALL` set to `TPNOREPLY`, `TPNOBLOCK`, or `TPNOTRAN`.
- Once a transaction has been marked “abort-only” for reasons other than timeout, a call to `TPGETRPLY` returns whatever value represents the local state of the call; that is, it returns either success or an error code that reflects the local condition.
- Once a handle is used with `TPGETRPLY` to retrieve a reply, or with `TPSEND` or `TPRECV` to report an error condition, it becomes invalid and any further reference to it returns `TPEBADDESC`. This rule is always observed, regardless of whether the code is running in transaction mode.
- Once a transaction is aborted, all outstanding transaction call handles (made without `TPNOTRAN`) become stale, and any further references to them return `TPEBADDESC`.

Transaction Errors

The following sections describe transaction-related errors.

Non-fatal Transaction Errors

When transaction errors occur, the system returns `TPETRAN` in `TP-STATUS`. The precise meaning of such an error, however, depends on the call that is returning it. [Table 11-3](#) lists the calls that return transaction errors and describes possible causes of them.

Table 11-3 Transaction Errors

Call	Cause
<code>TPBEGIN</code>	Usually caused by a transient system error that occur during an attempt to start the transaction. The problem may clear up with a repeated call.
<code>TPCANCEL</code>	Returns <code>TPETRAN</code> when called from a transaction.

Table 11-3 Transaction Errors

Call	Cause
TPRESUME	The Oracle Tuxedo system is unable to resume a global transaction because the caller is currently participating in work outside the global transaction with one or more resource managers. All such work must be completed before the global transaction can be resumed. The caller's state with respect to the local transaction is unchanged.
TPCONNECT, TPCALL, and TPACALL	<p>A call was made in transaction mode to a service that does not support transactions. Some services belong to server groups that access a database management system (DBMS) that, in turn, support transactions. Other services, however, do not belong to such groups. In addition, some services that support transactions may require interoperation with software that does not. For example, a service that prints a form may work with a printer that does not support transactions. Services that do not support transactions may not function as participants in a transaction.</p> <p>The grouping of services into servers and server groups is an administrative task. In order to determine which services support transactions, check with your application administrator.</p> <p>You can correct transaction-level errors at the application level by enabling the setting <code>TPSVCDEF-REF</code> or by accessing the service for which an error was returned outside of the transaction.</p>

Fatal Transaction Errors

When a fatal transaction error occurs, the application should explicitly abort the transaction by having the initiator call `TPABORT`. Therefore, it is important to understand the errors that are fatal to transactions. Three conditions cause a transaction to fail:

- The initiator or a participant in the transaction causes it to be marked “abort-only” for one of the following reasons:
 - `TPRETURN` encounters an error while processing its arguments; `TP-STATUS` is set to `TPESVCERR`.
 - The `TP-RETURN-VAL` to `TPRETURN` was set to `TPFAIL`; `TP-STATUS` is set to `TPESVCFAIL`.

- The type of the reply record is not known or not allowed by the caller and, as a result, success or failure cannot be determined; TP-STATUS is set to TPEOTYPE.
- The transaction times out; TP-STATUS is set to TPETIME.
- TPCOMMIT is called by a participant rather than by the originator of a transaction; TP-STATUS is set to TPEPROTO.

The only protocol error that is fatal to transactions is calling TPCOMMIT from the wrong participant in a transaction. This error can be corrected in the application during the development phase.

If TPCOMMIT is called after an initiator/participant failure or transaction timeout, the result is an implicit abort error. Then, because the commit failed, the transaction should be aborted.

If the system returns TPESVCERR, TPESVCFail, TPEOTYPE, or TPETIME for any communication call, the transaction should be aborted explicitly with a call to TPABORT. You need not wait for outstanding communication handles before explicitly aborting the transaction. However, because these communication handles are considered stale after the call is aborted, any attempt to access them after the transaction is terminated returns TPEBADDESC.

In the case of TPESVCERR, TPESVCFail, and TPEOTYPE, communication calls continue to be allowed as long as the transaction has not timed out. When these errors are returned, the transaction is marked abort-only. To preserve the results of any further work, you should call any communication functions with TPNOTRAN. By setting this flag, you ensure that the work performed for the transaction marked “abort-only” will not be rolled back when the transaction is aborted.

When a transaction timeout occurs, communication can continue, but communication requests cannot:

- Require replies
- Block
- Be performed on behalf of the caller’s transaction

Therefore, to make asynchronous calls, you must set TPNOREPLY, TPNOBLOCK, or TPNOTRAN.

Heuristic Decision Errors

The TPCOMMIT call may return TPEHAZARD or TPEHEURISTIC, depending on how TP-COMMIT-CONTROL is set.

If you set `TP-COMMIT-CONTROL` to `TP-CMT-LOGGED`, the application obtains control before the second phase of a two-phase commit is performed. In this case, the application may not be aware of a heuristic decision that occurs during the second phase.

`TPEHAZARD` or `TPEHEURISTIC` can be returned in a one-phase commit, however, if a single resource manager is involved in the transaction and it returns a heuristic decision or a hazard indication during a one-phase commit.

If you set `TP_COMMIT_CONTROL` to `TP_CMT_COMPLETE`, then the system returns `TPEHEURISTIC` if any resource manager reports a heuristic decision, and `TPEHAZARD` if any resource manager reports a hazard. `TPEHAZARD` specifies that a participant failed during the second phase of commit (or during a one-phase commit) and that it is not known whether a transaction completed successfully.

Transaction Timeouts

As described in [“Transaction Errors” on page 11-13](#), two types of timeouts can occur in an Oracle Tuxedo application: blocking and transaction. The following sections describe how various programming features are affected by transaction timeouts. Refer to [“Transaction Errors” on page 11-13](#) for more information on timeouts.

TPCOMMIT Call

What is the state of a transaction if a timeout occurs after a call to `TPCOMMIT`? If the transaction timed out and the system knows that it was aborted, the system reports these events by setting `TP-STATUS` to `TPEABORT`. If the status of the transaction is unknown, the system sets the error code to `TPETIME`.

When the state of a transaction is in doubt, you must query the resource manager. First, verify whether or not any of the changes that were part of the transaction were applied. Then you can determine whether the transaction was committed or aborted.

TPNOTRAN

When a process is in transaction mode and makes a communication call with `TPNOTRAN`, it prohibits the called service from becoming a participant in the current transaction. Whether the service request succeeds or fails has no impact on the outcome of the transaction. The transaction can still timeout while waiting for a reply that is due from a service, whether it is part of the transaction or not.

For additional information on using `TPNOTRAN`, refer to [“TPRETURN and TPFORWAR Calls” on page 11-17](#).

TPRETURN and TPFORWAR Calls

If you call a process while running in transaction mode, `TPRETURN` and `TPFORWAR` place the service portion of the transaction in a state that allows it to be either committed or aborted when the transaction completes. You can call a service several times on behalf of the same transaction. The system does not fully commit or abort the transaction until the initiator of the transaction calls `TPCOMMIT` or `TPABORT`.

Neither `TPRETURN` nor `TPFORWAR` should be called until all outstanding handles for the communication calls made within the service have been retrieved. If you call `TPRETURN` with outstanding handles for which `TP-RETURN-VAL` is set to `TPSUCCESS`, the system encounters a protocol error and returns `TPESVCERR` to the process waiting on `TPGETRPLY`. If the process is in transaction mode, the system marks the caller as “abort-only.” Even if the initiator of the transaction calls `TPCOMMIT`, the system implicitly aborts the transaction. If you call `TPRETURN` with outstanding handles for which `TP-RETURN-VAL` is set to `TPFAIL`, the system returns `TPESVCFAIL` to the process waiting on `TPGETRPLY`. The effect on the transaction is the same.

When you call `TPRETURN` while running in transaction mode, this function can affect the result of the transaction by the processing errors that it encounters or that are retrieved from the value placed in `TP-RETURN-VAL` by the application.

You can use `TPFORWAR` to indicate that success has been achieved up to a particular point in the processing of a request. If no application errors have been detected, the system invokes `TPFORWAR`; otherwise, the system invokes `TPRETURN` with `TPFAIL`. If you call `TPFORWAR` improperly, the system considers the call a processing error and returns a failed message to the requester.

tpterm() Function

Use the `TPTERM` call to remove a client context from an application.

If the client context is in transaction mode, the call fails with `TPEPROTO` returned in `TP-STATUS`, and the client context remains part of the application and in transaction mode.

When the call is successful, the client context is allowed no further communication or participation in transactions because the current thread of execution is no longer part of the application.

Resource Managers

When you use an ATMI call to define transactions, the Oracle Tuxedo system executes an internal call to pass any global transaction information to each resource manager participating in the transaction. When you call `TPCOMMIT` or `TPABORT`, for example, the system makes internal calls to direct each resource manager to commit or abort the work it did on behalf of the caller's global transaction.

When a global transaction has been initiated, either explicitly or implicitly, you should not make explicit calls to the resource manager's transaction calls in your application code. Failure to follow this transaction rule causes indeterminate results. You can use the `TPGETLEV` call to determine whether a process is already in a global transaction before calling the resource manager's transaction call.

Some resource managers allow programmers to configure certain parameters (such as the transaction consistency level) by specifying options available in the interface to the resource managers themselves. Such options are made available in two forms:

- Resource manager-specific function calls that can be used by programmers of distributed applications to configure options.
- Hard-coded options incorporated in the transaction interface supplied by the provider of the resource manager.

Consult the documentation for your resource managers for additional information.

The method of setting options varies for each resource manager. In the Oracle Tuxedo System SQL resource manager, for example, the `set transaction` statement is used to negotiate specific options (consistency level and access mode) for a transaction that has already been started by the Oracle Tuxedo system.

Sample Transaction Scenarios

The following sections provide some considerations for the following transaction scenarios:

- [Called Service in Same Transaction as Caller](#)
- [Called Service in Different Transaction with AUTOTRAN Set](#)
- [Called Service That Starts a New Explicit Transaction](#)

Called Service in Same Transaction as Caller

When a caller in transaction mode calls another service to participate in the current transaction, the following facts apply:

- `TPRETURN` and `TPFORWAR`, when called by the participating service, place that service's portion of the transaction in a state from which it can be either aborted or committed by the initiator.
- The success or failure of the called process affects the current transaction. If any fatal transaction errors are encountered by the participant, the current transaction is marked "abort-only."
- Whether or not the tasks performed by a successful participant are applied depends on the fate of the transaction. In other words, if the transaction is aborted, the work of all participants is reversed.
- `TPNOREPLY` cannot be used when calling another service to participate in the current transaction.

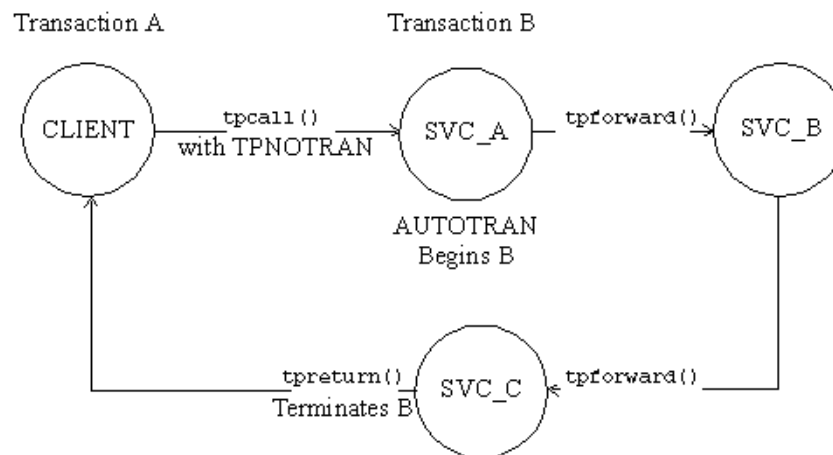

Called Service in Different Transaction with AUTOTRAN Set

If you issue a communication call with `TPNOTRAN` set and the called service is configured such that a transaction automatically starts when the service is called, the system places both the calling and called processes in transaction mode, but the two constitute different transactions. In this situation, the following facts apply:

- `TPRETURN` plays the initiator's transaction role: it terminates the transaction in the service in which the transaction was automatically started. Alternatively, if the transaction is automatically started in a service that terminates with `TPFORWAR`, the `TPRETURN` call issued in the last service in the forward chain plays the initiator's transaction role: it terminates the transaction. (For an example, refer to the figure called "[Transaction Roles of TPFORWAR and TPRETURN with AUTOTRAN](#)" on page 11-20.)

- Because it is in transaction mode, TPRETURN is vulnerable to the failure of any participant in the transaction, as well as to transaction timeouts. In this scenario, the system is more likely to return a failed message.
- The state of the caller's transaction is not affected by any failed messages or application failures returned to the caller.
- The caller's own transaction may timeout as the caller waits for a reply.
- If no reply is expected, the caller's transaction cannot be affected in any way by the communication call.

Figure 11-1 Transaction Roles of TPFORWAR and TPRETURN with AUTOTRAN

Called Service That Starts a New Explicit Transaction

If a communication call is made with TPNOTRAN, and the called service is not automatically placed in transaction mode by a configuration option, the service can define multiple transactions using explicit calls to TPBEGIN, TPCOMMIT, and TPABORT. As a result, the transaction can be completed before a call is issued to TPRETURN.

In this situation, the following facts apply:

- TPRETURN plays no transaction role; that is, the role of TPRETURN is always the same, regardless of whether transactions are explicitly defined in the service routine.

- `TPRETURN` can return any value in `TP-RETURN-VAL`, regardless of the outcome of the transaction.
- Typically, the system returns processing errors, record type errors, or application failure, and follows the normal rules for `TPESVCFail`, `TPEITYPE/TPEOTYPE`, and `TPESVCERR`.
- The state of the caller's transaction is not affected by any failed messages or application failures returned to the caller.
- The caller is vulnerable to the possibility that its own transaction may time out as it waits for its reply.
- If no reply is expected, the caller's transaction cannot be affected in any way by the communication call.

Oracle TUXEDO System-supplied Subroutines

The Oracle Tuxedo system-supplied subroutines, `TPSVRINIT` and `TPSVRDONE`, must follow certain rules when used in transactions.

The Oracle Tuxedo system server calls `TPSVRINIT` during initialization. Specifically, `TPSVRINIT` is called after the calling process becomes a server but before it starts handling service requests. If `TPSVRINIT` performs any asynchronous communication, all replies must be retrieved before the function returns; otherwise, the system ignores all pending replies and the server exits. If `TPSVRINIT` defines any transactions, they must be completed with all asynchronous replies retrieved before the function returns; otherwise, the system aborts the transaction and ignores all outstanding replies. In this case, the server exits gracefully.

The Oracle Tuxedo system server abstraction calls `TPSVRDONE` after it finishes processing service requests but before it exits. At this point, the server's services are no longer advertised, but the server has not yet left the application. If `TPSVRDONE` initiates communication, it must retrieve all outstanding replies before it returns; otherwise, pending replies are ignored by the system and the server exits. If a transaction is started within `TPSVRDONE`, it must be completed with all replies retrieved; otherwise, the system aborts the transaction and ignores the replies. In this case, too, the server exits.

Central Event Log

The central event log is a record of significant events in your Oracle Tuxedo application. Messages about these events are sent to the log by your application clients and services via the `USERLOG(3cbl)` routine.

Any analysis of the central event log must be provided by the application. You should establish strict guidelines for the events that are to be recorded in the `USERLOG(3cbl)`. Application debugging can be simplified by eliminating trivial messages.

For information on configuring the central event log on the Windows 2003 platform, refer to *Using Oracle Tuxedo ATMI on Windows*.

Log Name

The application administrator defines (in the configuration file) the absolute pathname that is used as the prefix of the name of the error message file on each machine. The `USERLOG(3cbl)` routine creates a date—in the form `mmddyy`, representing the month, day, and year—and adds this date to the pathname prefix, forming the full filename of the central event log. A new file is created daily. Thus, if a process sends messages to the central event log on succeeding days, the messages are written into different files.

Log Entry Format

Entries in the log consist of the following components:

- Tag consisting of:
 - Time of day (`hhmmss`)
 - Machine name (for example, the name returned by the `uname(1)` command on a UNIX system)
 - Name, process ID, and thread ID (which is 0 on platforms that do not support threads) of the thread calling `USERLOG(3cbl)`
 - Context ID of the thread calling `USERLOG(3cbl)`

- Message text

The text of each message is preceded by the catalog name and number of that message.

For example, suppose that a security program executes the following call at 4:22:14pm on a UNIX machine called `mach1` (as returned by the `uname` command):

```
01 LOG-REC PIC X(15) VALUE "UNKNOWN USER ".
01 LOGREC-LEN PIC S9(9) VALUES IS 13.
CALL "USERLOG" USING LOG-REC LOGREC-LEN TPSTATUS-REC.
```

The resulting log entry appears as follows:

```
162214.mach1!security.23451: UNKNOWN USER
```

In this example, the process ID for security is 23451.

If the preceding message was generated by the Oracle Tuxedo system (rather than by the application), it might appear as follows:

```
162214.mach1!security.23451: COBAPI_CAT: 999: UNKNOWN USER
```

In this case, the message catalog name is COBAPI_CAT and the message number is 999.

If the message is sent to the central event log while the process is in transaction mode, other components are added to the tag in the user log entry. These components consist of the literal string gtrid followed by three long hexadecimal integers. The integers uniquely identify the global transaction and make up what is referred to as the global transaction identifier, that is, the gtrid. This identifier is used mainly for administrative purposes, but it also appears in the tag that prefixes the messages in the central event log. If the system writes the message to the central event log in transaction mode, the resulting log entry appears as follows:

```
162214.mach1!security.23451: gtrid x2 x24e1b803 x239:
UNKNOWN USER
```

Writing to the Event Log

To write a message to the event log, you must perform the following steps:

- Assign the error message you wish to write to the log to a record and use the record name as the argument to the call.
- Specify the literal text of the message within double quotes, as the argument to the `USERLOG(3cbl)` call, as shown in the following example:

```
01 TPSTATUS-REC.
   COPY TPSTATUS.
01 LOGMSG      PIC X(50).
01 LOGMSG-LEN  PIC S9(9) COMP-5.
. . .
CALL "TPOpen" USING TPSTATUS-REC.
IF NOT TPOK
    MOVE "TPSVRINIT: Cannot Open Data Base" TO LOGMSG
    MOVE 43 LOGMSG-LEN
    CALL "USERLOG" USING LOGMSG
                        LOGMSG-LEN
                        TPSTATUS-REC.
. . .
```

In this example, the message is sent to the central event log if `TPOPEN(3cbl)` returns -1.

COBOL Language Bindings for the Workstation Component

This topic includes the following sections:

- [UNIX Bindings](#)
- [Microsoft Windows Bindings](#)

Refer to *Using the Oracle Tuxedo Workstation Component* for more information on the Workstation platform.

UNIX Bindings

The following sections describe how to write and build client programs, and set appropriate environment variables when developing, in COBOL, an Oracle Tuxedo application on a UNIX platform.

Writing Client Programs

You can develop COBOL client programs for a UNIX platform in the same way that you develop COBOL clients in the Oracle Tuxedo administrative domain. All ATMI calls are available.

Building Client Programs

To compile and link-edit Workstation client programs, use the `buildclient(1)` command. If you are building a UNIX Workstation client on the native node, use the `-w` option to have the client built using the Workstation libraries.

If you are building a client on a native node, and both native and Workstation libraries are present, the native libraries are used by default. In this case, specifying the `-w` option ensures that the correct libraries for a Workstation client are used.

On a workstation, where only the Workstation libraries are present, it is not necessary to specify `-w`.

[Listing 12-3](#) shows how to use the `buildclient` command on a native node.

Listing 12-1 Example of Running `buildclient` on a UNIX Platform

```
ALTCC=cobcc ALTFLAGS="-I /APPDIR/include"
COBCPY=$TUXDIR/cobinclude
COBOPT="-C ANS85 -C ALIGN=8 -C NOIBMCOMP -C TRUNC=ANSI -C OSEXT=cbl"
export COBOPT COBCPY ALTCC ALTFLAGS
buildclient -C -w -o empclient -f name.cbl -f "userlib1.a userlib2.a"
```

The `-o` option enables you to specify a name for your output file. Input files specified with the `-f` option are linked before system libraries.

As illustrated, the `TUXDIR` environment variable must be used to ensure that the `buildclient` command can locate system libraries. Be sure that you have defined `TUXDIR`. The `CC` environment variable defaults to `cc`, but can be set to another compiler through `ALTCC`.

Setting Environment Variables

Workstation clients make use of several environment variables.

[Table 12-1](#) lists the environment variables that are checked by `TPINITIALIZE` when a Workstation client attempts to join an application.

Table 12-1 Environment Variables Checked by TPINITIALIZE on a UNIX Platform

Environment Variable	Description
WSENVFILE	Name of a file containing environment variable settings to be used in the client's environment.
WSNADDR	Network address of the Workstation listener process through which the client gains access to the application. Use the value specified in the application configuration file for the Workstation listener to be called. If the value begins with the characters 0x, the system interprets it as a string of hexadecimal digits; otherwise, the system interprets it as ASCII characters.
WSDEVICE	Name of the device to be used to access the network. Not required by all transport layer interfaces.
WSTYPE	Workstation type. Used by TPINITIALIZE when that call is invoked by a Workstation client to negotiate encode/decode responsibilities with the native site. If you do not specify WSTYPE, the system performs encoding, even if WSTYPE is not specified on the native site, either. You must explicitly specify the same WSTYPE value for both the native and Workstation client sites to ensure that the encode/decode feature is turned off.
WSRPLYMAX	Maximum amount of core memory that the ATMI uses for buffering application replies before dumping them to disk. Used by TPINITIALIZE. The default system limit is 256,000 bytes. Whether you should use WSRPLYMAX to set a lower limit depends on the amount of memory available on your machine. Writing replies to disk causes a substantial reduction in performance.
WSFADDR	The network address used by the Workstation client when connecting to the Workstation listener or Workstation handler. This variable, along with the WSFRANGE variable, determines the range of TCP/IP ports to which a Workstation client will attempt to bind before making an outbound connection. This address must be a TCP/IP address.
WSFRANGE	The range of TCP/IP ports to which a Workstation client process attempts to bind before making an outbound connection. The WSFADDR parameter specifies the base address of the range. The default is 1.

Other environment variables may be needed by Workstation COBOL clients on a UNIX workstation, depending on which components of the Oracle Tuxedo system are being used.

Note: MicroFocus delivers `LIBNSL.a` as a shared object, which is required by `buildclient` when linking a Workstation client. Because MicroFocus COBOL does not support shared objects on UNIX 3.2, Workstation for UNIX 3.2 is not supported.

Microsoft Windows Bindings

The following sections describe how to write and build client programs, build ACCEPT/DISPLAY clients, block network behavior, and restore the network environment when developing, in COBOL, an Oracle Tuxedo application for the Microsoft Windows platform.

Writing Client Programs

All program-specific ATMI calls are available.

Building Client Programs

To compile the COBOL source files that call the ATMI, you must use the COBOL compiler with the `LITLINK` option. To linkedit the Workstation client object files, use the `buildclient(1)` command. While the syntax of the command is straightforward, the usage varies according to the compilation system used.

[Listing 12-2](#) shows how to use the `buildclient` command.

Listing 12-2 Example of Running `buildclient` on a Windows Platform

```
COBCPY=C:\TUXEDO\COBINC
COBDIR=C:\COBOL\LBR;C:\COBOL\EXEDLL
PATH=C:\COBOL\EXEDLL;...
TUXDIR=C:\tuxedo
LIB=C:\NET\TOOLKIT\LIB;C:\MSVC\LIB;C:\TUXEDO\LIB;C:\COBOL\LIB
buildclient -C -o EMP.EXE -f EMP -f "/NOD/NOI/NOE/CO/SE:300" -l WLIBSOCK
```

For Windows NT:

```
buildclient -C -o EMP.EXE -f empobj
```

[Table 12-2](#) describes the `buildclient` command options used in the preceding example.

Table 12-2 buildclient Command Options for Windows Platform

Option	Description
<code>-o name</code>	Name of the executable file being created. The default is <code>client.exe</code> .
<code>-f firstfiles</code>	One or more object files to be included before the Oracle Tuxedo libraries. You can use the <code>-f</code> option to pass options to the compiler or linker. To specify more than one filename, enter a list of files after <code>-f</code> , using white space to separate filenames and double quotation marks around the list. You can also specify multiple filenames using multiple occurrences of the <code>-f</code> option on the command line.
<code>-l libfiles</code>	Libraries to be included after the Oracle Tuxedo libraries. To specify more than one filename, you must separate the names by white space and enclose the list in quotation marks. You can also specify multiple filenames using multiple occurrences of the <code>-l</code> option on the command line.

Building ACCEPT/DISPLAY Clients

The following example shows how to build an executable client for an ACCEPT/DISPLAY application, such as CSIMPAPP.

Listing 12-3 Building ACCEPT/DISPLAY clients

```

a) compile the COBOL module and create a file.obj
    cobol file.cbl omf(obj) litlink;
b) use the following link statement
    link FILE+cblwinaf,,\
    wcobatmi+cobws+wtuxws+ \
    lcobol+lcoboldw+cobw+cobfp87w+ \
    wlibsock,FILE.def /nod/noe;
For Windows NT the link statement is:
    cbllink -oEMP.exe EMP.obj \
    cobws.lib ncobatmi.lib wtuxws32.lib \
    libcmt.lib user32.lib

```
